7 **Abstract.** In Part I we have proposed a multilinear algebra framework to solve 0-dimensional
8 systems of polynomial equations with simple roots. We extend the framework to incorporate multiple
9 roots: a block term decomposition (BTD) of the null space of the Macaulay matrix reveals the dual
10 (sub)space of a disjoint root in each term. The BTD is the joint triangularization of multiplication
11 tables and a three-way generalization of the Jordan canonical form in the matrix case, intimately
12 related to the border rank of a tensor. We hint at and illustrate flexible numerical optimization-based
13 algorithms.

14 **Key words.** system of polynomial equations, multilinear algebra, block term decomposition,
15 border rank, Macaulay matrix, multiplication table

17 **1. Introduction.** Systems of polynomial equations arise often in science and engi-
18 neering. Solving such a system means finding all the common roots of the polynomi-
19 als. Many methods have become available to solve systems of polynomial equations:
20 algebraic geometry-based computer algebra methods, e.g., [5], Polynomial Homotopy
21 Continuation (PHC), e.g., [39, 4], (Macaulay) resultant- and linear algebra-based
22 methods [21, 37, 36] including, e.g., Numerical Polynomial Algebra (NPA) [28, 34]
23 and Polynomial Numerical Linear Algebra (PNLA) [1, 14], etc.

24 A higher-order tensor in multilinear algebra is a multi-way generalization of a one-
25 way vector and a two-way matrix in linear algebra. Tensor decompositions like the
26 Canonical Polyadic Decomposition (CPD) and the Block Term Decomposition (BTD)
27 are then generalizations of matrix decompositions. Despite the natural generalization,
28 multilinear algebra exhibits striking differences with linear algebra. First, a tensor
29 that has rank greater than R is said to have border rank R if it can be approximated
30 arbitrarily well by a (sequence of) rank- R tensor(s) [13]. [32] shows that this phe-
31 nomenon can be seen as a multi-way generalization of approximate diagonalization
32 of a non-diagonalizable matrix and that the limit point of the approximating rank- R
33 sequence can be seen as a multi-way generalization of the Jordan canonical form.
34 Second, the rank of a tensor depends on the field considered for the factor entries.

35 For a tensor in $\mathbb{R}^{I_1 \times I_2 \times \dots \times I_N}$ chosen at random according to continuous distribu-
 36 tions (e.g., i.i.d. Gaussian entries), more than one distinct value of the rank occurs
 37 with positive probability. These rank values are called typical.

38 In [38] we presented a multilinear algebra framework to formulate and solve 0-
 39 dimensional polynomial root-finding problems, the solutions of which are isolated and
 40 finite in number. This discussion was limited to systems with only simple roots.
 41 For such systems we derived a connection between the null space of the Macaulay
 42 matrix and multidimensional harmonic retrieval (MHR). By jointly exploiting the
 43 multiplicative shift invariance in the different variables, we obtained a third-order
 44 tensor CPD that reveals the common roots.

45 In this companion paper we discuss systems of polynomial equations that are
 46 allowed to have roots with multiplicity greater than 1. Rather than just a single integer
 47 for the multiplicity, the multiplicity structure (dual space) of a multiple root is an
 48 essential means in providing characteristics of the root [6]. The dual spaces manifest
 49 themselves in the null space of the Macaulay matrix. If a system has roots with
 50 multiplicity greater than 1, the basis of the null space of the Macaulay matrix does
 51 not fully exhibit multiplicative shift invariance anymore. Consequently, we cannot
 52 derive a third-order tensor CPD that reveals the roots. Instead, we will derive a
 53 third-order tensor BTD that reveals the dual (sub)spaces of the disjoint roots.

54 In [38] we explained that the multiplicative shift invariance-expressing CPD can
 55 be seen in terms of the joint diagonalization of NPA’s multiplication tables. In this
 56 companion paper we will explain that the BTD generalization can be seen in terms of
 57 the joint block diagonalization/triangularization of the multiplication tables. Further,
 58 BTD offers a three-way generalization of the Jordan canonical form of the Eigenvalue
 59 Decomposition (EVD) in NPA. Such connections emphasize the unifying power of
 60 the multilinear algebra framework and its ability to help us understand the “roots”
 61 of polynomial systems and multilinear algebra more profoundly. Including BTB, our
 62 approach is able to (recursively) detect various (nested) structures in the null space of
 63 the Macaulay matrix. The multilinear approach opens a whole new range of numerical
 64 optimization techniques to solve systems of polynomial equations.

65 The paper is organized as follows. [Section 2](#) will review our notation and introduce
 66 some necessary definitions. [Section 3](#) will introduce the CPD and BTB as important
 67 tensor decompositions for this study, present a new uniqueness result for a BTB with
 68 special structure, and will update the structure of the null space of the Macaulay
 69 matrix from the “simple root case” to the “case of roots with multiplicities”. In
 70 [section 4](#) we will then establish that the formerly resulting third-order tensor CPD
 71 needs to be understood as a special case of a third-order tensor BTB that also covers
 72 the more general case of roots with multiplicities. To develop insight, the emphasis
 73 is on the affine case, but the results can easily be extended to the projective case.
 74 [Section 5](#) will further make connections between the BTB and the border rank of the
 75 higher-tensor tensor and between the BTB and the possible difference between the
 76 tensor’s rank over the complex field and its rank over the real field. In [section 6](#) we
 77 propose polynomial root-finding algorithms based on the insights from the previous
 78 sections. [Section 7](#) presents the results of numerical experiments and [section 8](#) will
 79 summarize our findings.

80 **2. Notation.** We give a quick summary of our notation. For more details the
 81 reader is referred to [38].

82 **2.1. Higher-order tensors.** Scalars, vectors, matrices and tensors are denoted
 83 by italic, boldface lowercase, boldface uppercase and calligraphic letters respectively:

84 $a \in \mathbb{C}$, $\mathbf{a} \in \mathbb{C}^{I_1}$, $\mathbf{A} \in \mathbb{C}^{I_1 \times I_2}$ and the N th-order tensor $\mathcal{A} \in \mathbb{C}^{I_1 \times \dots \times I_N}$. This paper
 85 will not surpass the third-order case. $a_{i_1} = \mathbf{a}(i_1) = (\mathbf{a})_{i_1}$ is the i_1 th entry of vector
 86 \mathbf{a} . $a_{i_1, i_2} = \mathbf{A}(i_1, i_2) = (\mathbf{A})_{i_1, i_2}$ is equal to the entry of matrix \mathbf{A} with row index i_1
 87 and column index i_2 . $\mathbf{a}_{i_2} = \mathbf{A}(:, i_2) = (\mathbf{A})_{i_2}$ denotes the i_2 th column of \mathbf{A} . Likewise
 88 for the entries (a_{i_1, i_2, i_3}) and fibers ($\mathcal{A}(i_1, :, :)$, $\mathcal{A}(:, i_2, :)$, $\mathcal{A}(:, :, i_3)$) of a tensor \mathcal{A} ; the
 89 vector obtained when all but the n th index of \mathcal{A} are kept fixed, is called a mode- n
 90 fiber of \mathcal{A} . The i_3 th matrix slice $\mathcal{A}(:, :, i_3)$ of \mathcal{A} is denoted as \mathbf{A}_{i_3} . \cdot^* , \cdot^T , \cdot^H , \cdot^{-1}
 91 and \cdot^\dagger denote the complex conjugate, transpose, Hermitian transpose, inverse and
 92 Moore–Penrose pseudoinverse, respectively.

93 $\mathbf{D} = \text{diag}(\mathbf{d})$ represents a diagonal matrix with the vector \mathbf{d} on its diagonal and
 94 $\mathbf{D}_i(\mathbf{C}) = \text{diag}(\mathbf{C}(i, :))$ holds the i th row of the matrix \mathbf{C} . \mathbf{I}_I is the identity matrix
 95 of order $I \times I$. $\text{span}(\{\mathbf{a}_1, \dots, \mathbf{a}_I\})$ is the span of the vectors \mathbf{a}_1 through \mathbf{a}_I . $\text{col}(\mathbf{A})$,
 96 $\text{row}(\mathbf{A})$ and $\text{null}(\mathbf{A})$ are used to denote the column, row and right null space of
 97 \mathbf{A} , respectively. $r_{\mathbf{A}}$ denotes the rank of \mathbf{A} . Lastly, the Kronecker and Khatri–Rao
 98 products are denoted by \otimes and \odot , respectively, and $\dot{+}$ is used to denote the direct
 99 sum of subspaces.

100 A third-order tensor \mathcal{A} is vectorized to $\text{vec}(\mathcal{A})$ by vertically stacking all entries
 101 a_{i_1, i_2, i_3} such that i_3 varies slowest and i_1 varies fastest:

102 $a_{i_1, i_2, i_3} = (\text{vec}(\mathcal{A}))_{(i_3-1)I_2I_1 + (i_2-1)I_1 + i_1}$. The matrix representation $\mathbf{A}_{[1;3,2]}$ is ob-
 103 tained by stacking the mode-1 fibers of \mathcal{A} as columns into a matrix, in such a way
 104 that i_2 varies fastest along the second dimension: $a_{i_1, i_2, i_3} = (\mathbf{A}_{[1;3,2]})_{i_1, (i_3-1)I_2 + i_2}$.

105 The mode-1 product $\mathcal{C} = \mathcal{A} \cdot_1 \mathbf{B} \in \mathbb{C}^{J \times I_2 \times I_3}$ of a tensor $\mathcal{A} \in \mathbb{C}^{I_1 \times I_2 \times I_3}$ and a ma-
 106 trix $\mathbf{B} \in \mathbb{C}^{J \times I_1}$ then has the matrix representation $\mathbf{C}_{[1;3,2]} = \mathbf{B}\mathbf{A}_{[1;3,2]}$, i.e. it is
 107 the result of multiplying all mode-1 fibers of \mathcal{A} from the left with \mathbf{B} . Other matrix
 108 representations and according products are defined analogously.

109 The mode- n rank $R_n = \text{rank}_n(\mathcal{A})$ is the dimension of the mode- n fiber space, i.e.
 110 $R_n = r_{\mathbf{A}_{[n; \bullet]}}$, in which \bullet indicates that the order of the indices different from n does
 111 not matter. The tuple $\text{rank}_{\boxplus}(\mathcal{A}) = (R_1, R_2, R_3)$ is called the multilinear rank of \mathcal{A} .
 112 The outer product $\mathcal{T} = \mathbf{a} \otimes \mathbf{b} \otimes \mathbf{c}$ of nonzero vectors \mathbf{a} , \mathbf{b} , \mathbf{c} yields a rank-1 tensor
 113 with entries $t_{i_1, i_2, i_3} = a_{i_1} b_{i_2} c_{i_3}$. The minimal number of rank-1 terms that sum to a
 114 particular tensor \mathcal{A} is called the rank of \mathcal{A} and denoted as $r_{\mathcal{A}}$.

115 **2.2. Polynomial equations.** Let us consider the system of polynomial equa-
 116 tions

$$117 \quad (1) \quad \begin{cases} f_1(x_1, \dots, x_n) = 0 \\ \vdots \\ f_s(x_1, \dots, x_n) = 0 \end{cases}$$

118 in n complex variables x_j , stacked in the vector $\mathbf{x} \in \mathbb{C}^n$. A monomial $\mathbf{x}^\alpha = \prod_{j=1}^n x_j^{\alpha_j}$
 119 is defined by an exponent vector α . The degree of a monomial is defined as $\text{deg}(\mathbf{x}^\alpha) =$
 120 $\sum_{j=1}^n \alpha_j$. There exist several schemes for ordering monomials by their exponent vec-
 121 tor. As in the companion paper [38], we will adopt the degree negative lexicographic
 122 order. The monomials $\mathbf{x}^\alpha < \mathbf{x}^\beta$ are ordered by the degree negative lexicographic
 123 order if one of the following two conditions is satisfied: (i) $\text{deg}(\mathbf{x}^\alpha) < \text{deg}(\mathbf{x}^\beta)$; or (ii)
 124 $\text{deg}(\mathbf{x}^\alpha) = \text{deg}(\mathbf{x}^\beta)$ and the leftmost nonzero entry of $\beta - \alpha$ is negative.

125 A polynomial $f(x_1, \dots, x_n) = \sum_{l=1}^p f_l \mathbf{x}^{\alpha_l}$ is characterized by a coefficient vector
 126 \mathbf{f} . The degree d_i of a polynomial f_i in (1) is the degree of the monomial with the
 127 highest degree in f_i . The ring of all polynomials in n variables is denoted by \mathcal{C}^n . The
 128 vector space \mathcal{C}_d^n is the subset of \mathcal{C}^n that contains all polynomials up to degree d . Its

129 dimension is given by

$$130 \quad q(d) = \dim \mathcal{C}_d^n = \binom{n+d}{n}.$$

131 A polynomial is said to be homogeneous if all its monomials have the same degree.
 132 A polynomial f can be homogenized to a polynomial f^h by multiplying each monomial
 133 $\mathbf{x}_l^{\alpha_l}$ in f with a power β_l of x_0 , such that $\deg(x_0^{\beta_l} \mathbf{x}_l^{\alpha_l}) = d$ for all l . The ring
 134 (vector space) of all homogeneous polynomials in $n+1$ variables (up to degree d) is
 135 denoted by \mathcal{P}^n (\mathcal{P}_d^n). The projective space \mathbb{P}^n is the set of equivalence classes on
 136 $\mathbb{C}^{n+1} \setminus \{\mathbf{0}\}$: $(x'_0 \ x'_1 \ \dots \ x'_n)^T \sim (x_0 \ x_1 \ \dots \ x_n)^T$ if there exists a $\lambda \in \mathbb{C}$ such
 137 that $(x'_0 \ x'_1 \ \dots \ x'_n)^T = \lambda (x_0 \ x_1 \ \dots \ x_n)^T$. Points with $x_0 = 0$ cannot be
 138 normalized to their affine counterpart $(1 \ \frac{x_1}{x_0} \ \dots \ \frac{x_n}{x_0})^T$: they are points at infinity.

139 The degree of (1) is $d_0 = \max_{i=1}^s d_i$. The set of all roots of (1) is called the solution
 140 set. Under the same assumptions as in [38] that (1) is a square system ($n = s$) with
 141 a 0-dimensional solution set, the number of roots in the projective space, counting
 142 multiplicities, is given by the Bézout number

$$143 \quad m = \prod_{i=1}^n d_i.$$

144 If (1) has multiple roots, $m_0 < m$ denotes the number of disjoint roots. The m_0
 145 distinct roots of (1) will be denoted by $(x_0^{(k)} \ x_1^{(k)} \ x_2^{(k)} \ \dots \ x_n^{(k)})^T \in \mathbb{P}^n$, $k = 1 : m_0$.
 146 m_0 .

147 **3. Tensor decompositions, Macaulay null space and harmonic structure:**
 148 **from simple roots to roots with multiplicities.** Similar to the way [38]
 149 was organized, in this section we display the ingredients from the study of tensor
 150 decompositions, sets of polynomial equations and harmonic retrieval that we will
 151 combine in our derivation. To allow roots with multiplicities, we will not only need
 152 CPD, as in [38], but also a particular type of BTD (Section 3.1). We also need to
 153 discuss the multiplicity structure of a root (Section 3.2). For handling roots with
 154 multiplicities, we need to take the step from the multivariate Vandermonde structure
 155 in [38] to a "confluent" extension (Section 3.3).

156 3.1. Tensor decompositions.

157 **3.1.1. CPD.** An R -term polyadic decomposition (PD) expresses a tensor $\mathcal{T} \in$
 158 $\mathbb{C}^{I_1 \times I_2 \times I_3}$ as a sum of R rank-1 terms

$$159 \quad (2) \quad \mathcal{T} = \llbracket \mathbf{A}, \mathbf{B}, \mathbf{C} \rrbracket \stackrel{\text{def}}{=} \sum_{r=1}^R \mathbf{a}_r \otimes \mathbf{b}_r \otimes \mathbf{c}_r.$$

The matrices $\mathbf{A} \in \mathbb{C}^{I_1 \times R}$, $\mathbf{B} \in \mathbb{C}^{I_2 \times R}$ and $\mathbf{C} \in \mathbb{C}^{I_3 \times R}$ are called factor matrices. If R
 is minimal, then the PD is a Canonical Polyadic Decomposition (CPD) and $R = r_{\mathcal{T}}$
 is the rank of \mathcal{T} . Equation (2) can be expressed in an entry-wise manner as

$$t_{i_1 i_2 i_3} = \sum_{r=1}^R a_{i_1 r} b_{i_2 r} c_{i_3 r}, \quad i_1 = 1 : I_1, i_2 = 1 : I_2, i_3 = 1 : I_3.$$

In a slice-wise manner, (2) can be written as

$$\mathbf{T}_{i_3} = \mathbf{A} \mathbf{D}_{i_3}(\mathbf{C}) \mathbf{B}^T, \quad i_3 = 1 : I_3.$$

160 In matricized format, (2) can be written as

$$161 \quad \mathbf{T}_{[1,2;3]} = \sum_{r=1}^R (\mathbf{a}_r \otimes \mathbf{b}_r) \mathbf{c}_r^T = (\mathbf{A} \odot \mathbf{B}) \mathbf{C}^T.$$

162 A CPD can only be unique up to permutation of the rank-1 terms and scaling/counter-
163 scaling of the vectors within the same term (i.e. we can allow $\mathbf{a}_r \leftarrow \mathbf{a}_r \alpha_r$, $\mathbf{b}_r \leftarrow \mathbf{b}_r \beta_r$,
164 $\mathbf{c}_r \leftarrow \mathbf{c}_r \gamma_r$ with $\alpha_r \beta_r \gamma_r = 1$).

165 **3.1.2. BTD.** Block term decomposition (BTD) generalizes PD in the sense that
166 the terms do not need to be rank-1 (i.e. have multilinear rank $(1, 1, 1)$) but only need
167 to have low multilinear rank [8, 9, 12]. Specifically, in this paper, we will deal with
168 the BTD

Fig. 1: BTB of a tensor \mathcal{T} is a decomposition in terms that have low multilinear rank.

$$169 \quad (3) \quad \mathcal{T} = \sum_{r=1}^R [\mathcal{G}_r; \mathbf{A}_r, \mathbf{B}_r, \mathbf{C}_r] \stackrel{\text{def}}{=} \sum_{r=1}^R \mathcal{G}_r \cdot_1 \mathbf{A}_r \cdot_2 \mathbf{B}_r \cdot_3 \mathbf{C}_r,$$

170 in which $\mathcal{G}_r \in \mathbb{C}^{\mu_r \times \mu_r \times \mu_r}$ is multilinear rank- (μ_r, μ_r, μ_r) and the matrices $\mathbf{A}_r \in$
171 $\mathbb{C}^{I_1 \times \mu_r}$, $\mathbf{B}_r \in \mathbb{C}^{I_2 \times \mu_r}$ and $\mathbf{C}_r \in \mathbb{C}^{I_3 \times \mu_r}$ have full column rank, $r = 1 : R$, implying that
172 (3) is a decomposition into a sum of multilinear rank- (μ_r, μ_r, μ_r) terms. Throughout
173 the paper we will consider only those decompositions of the form (3) for which the
174 matrices

$$175 \quad (4) \quad \mathbf{B} \stackrel{\text{def}}{=} (\mathbf{B}_1 \ \dots \ \mathbf{B}_R) \in \mathbb{C}^{I_2 \times \sum_{r=1}^R \mu_r} \quad \text{and} \quad \mathbf{C} \stackrel{\text{def}}{=} (\mathbf{C}_1 \ \dots \ \mathbf{C}_R) \in \mathbb{C}^{I_3 \times \sum_{r=1}^R \mu_r}$$

176 have full column rank. We say that \mathcal{T} is indecomposable if \mathcal{T} does not admit a
177 decomposition of the form (3) with $R \geq 2$ terms and such that condition (4) holds.

178 We say that decomposition (3) of \mathcal{T} into a sum of R indecomposable multilinear
179 rank- (μ_r, μ_r, μ_r) terms is unique if any other decomposition of \mathcal{T} into a sum of \tilde{R}
180 indecomposable multilinear rank- $(\tilde{\mu}_r, \tilde{\mu}_r, \tilde{\mu}_r)$ terms necessarily coincides with (3) up

181 to permutation of the terms provided that $\sum_{r=1}^{\tilde{R}} \tilde{\mu}_r = \sum_{r=1}^R \mu_r$. The counterpart

182 of the CPD scaling/counterscaling ambiguity is that we can allow $\mathbf{A}_r \leftarrow \mathbf{A}_r \mathbf{M}_r^{(1)}$,

183 $\mathbf{B}_r \leftarrow \mathbf{B}_r \mathbf{M}_r^{(2)}$, $\mathbf{C}_r \leftarrow \mathbf{C}_r \mathbf{M}_r^{(3)}$, in which $\mathbf{M}_r^{(1)} \in \mathbb{C}^{\mu_r \times \mu_r}$, $\mathbf{M}_r^{(2)} \in \mathbb{C}^{\mu_r \times \mu_r}$, $\mathbf{M}_r^{(3)} \in$

184 $\mathbb{C}^{\mu_r \times \mu_r}$ are invertible, if the transformation is compensated by $\mathcal{G}_r \leftarrow \mathcal{G}_r \cdot_1 (\mathbf{M}_r^{(1)})^{-1} \cdot_2$

185 $(\mathbf{M}_r^{(2)})^{-1} \cdot_3 (\mathbf{M}_r^{(3)})^{-1}$ [9].

186 The following theorem presents a sufficient condition for uniqueness of BTB (3).

187 If $\mu_1 = \dots = \mu_R = 1$, that is, in the case of the CPD, **Theorem 3.1** reduces to [38,

188 **Theorem 3.1**].

189 THEOREM 3.1. Let $\mathcal{T} \in \mathbb{C}^{I_1 \times I_2 \times I_3}$ admit decomposition (3) into a sum of multi-
 190 linear rank- (μ_r, μ_r, μ_r) terms. Assume that

191 (5) the matrices \mathbf{B} and \mathbf{C} defined in (4) have full column rank,

192 (6) the matrix $[\mathbf{A}_1(:, 1) \dots \mathbf{A}_R(:, 1)]$ does not have proportional columns,

194 and that the core tensors $\mathcal{G}_r \in \mathbb{C}^{\mu_r \times \mu_r \times \mu_r}$ have slices $\mathcal{G}_r(l+1, :, :) = \mathcal{G}_r(:, l+1, :) \in$
 195 $\mathbb{C}^{\mu_r \times \mu_r}, l = 0 : \mu_r - 1$, which are upper-triangular or, if $l = 0$, equal to \mathbf{I}_{μ_r} . Then
 196 BTD (3) is unique.

197 *Proof.* The proof is given in Appendix A. \square

198 Moreover, if the assumptions of Theorem 3.1 hold, the argumentation in Appendix A
 199 gives a way to compute the BTD and its factor matrices algebraically by means of
 200 a block-diagonalization by a similarity transform. As in Appendix A we consider
 201 w.l.o.g. a tensor \mathcal{T} where \mathbf{B}, \mathbf{C} are square, i.e., the second mode dimension of \mathcal{T} is
 202 equal to the third one: $I_2 = I_3 = m = \mu_1 + \dots + \mu_R$. For \mathcal{T} with larger second
 203 and third mode dimensions, this can be achieved by, e.g., a compression using the
 204 multilinear singular value decomposition (MLSVD)¹ [11]. Define two "slice mixtures"
 205 $\mathbf{T}_1 \stackrel{\text{def}}{=} \mathcal{T} \cdot_1 \mathbf{f}^T$ and $\mathbf{T}_2 \stackrel{\text{def}}{=} \mathcal{T} \cdot_1 \mathbf{g}^T \in \mathbb{C}^{m \times m}$, where $\mathbf{f}, \mathbf{g} \in \mathbb{C}^{I_1}$ are two generic vectors.
 206 Because

$$207 \quad (7) \quad \mathcal{T} \cdot_1 \mathbf{h}^T = \mathbf{B} \cdot \text{Blockdiag}(\mathcal{G}_1 \cdot_1 (\mathbf{h}^T \mathbf{A}_1), \dots, \mathcal{G}_{m_0} \cdot_1 (\mathbf{h}^T \mathbf{A}_R)) \cdot \mathbf{C}^T$$

208 for any vector $\mathbf{h} \in \mathbb{C}^{I_1}$, the factor matrix \mathbf{B} is, up to the intrinsic indeterminacies
 209 mentioned above, given by the block-diagonal decomposition²

$$210 \quad \mathbf{T}_2 \mathbf{T}_1^{-1} = \mathbf{B} \begin{pmatrix} \mathbf{D}_1 & & \\ & \ddots & \\ & & \mathbf{D}_R \end{pmatrix} \mathbf{B}^{-1}, \quad \mathbf{D}_r \stackrel{\text{def}}{=} (\mathcal{G}_r \cdot_1 \mathbf{g}^T \mathbf{A}_r)(\mathcal{G}_r \cdot_1 \mathbf{f}^T \mathbf{A}_r)^{-1} \in \mathbb{C}^{\mu_r \times \mu_r}.$$

212 The factor matrix \mathbf{C} can be obtained as $\mathbf{C} = \mathbf{T}_1 \mathbf{B}^{-T}$ (this follows easily from (7)),
 213 again up to the intrinsic indeterminacies. The above block-diagonalization of $\mathbf{T}_2 \mathbf{T}_1^{-1}$
 214 can in practice be computed, e.g., from a Schur decomposition of $\mathbf{T}_2 \mathbf{T}_1^{-1}$, see [19,
 215 §7.6.3]. It also returns the partition of \mathbf{B} into the blocks $\mathbf{B}_r \in \mathbb{C}^{m \times \mu_r}$, and conse-
 216 quently also the partitioning of \mathbf{C} into blocks $\mathbf{C}_r \in \mathbb{C}^{m \times \mu_r}$, with correct column sizes.
 217 We have

$$218 \quad \mathcal{T} \cdot_2 \mathbf{B}^{-1} \cdot_3 \mathbf{C}^{-1} = \sum_{r=1}^R \mathcal{G}_r \cdot_1 \mathbf{A}_r \cdot_2 (\mathbf{B}^{-1} \mathbf{B}_r) \cdot_3 (\mathbf{C}^{-1} \mathbf{C}_r) = \sum_{r=1}^R \mathcal{G}_r \cdot_1 \mathbf{A}_r \cdot_2 \begin{pmatrix} 0 \\ \mathbf{I}_{\mu_r} \\ 0 \end{pmatrix} \cdot_3 \begin{pmatrix} 0 \\ \mathbf{I}_{\mu_r} \\ 0 \end{pmatrix},$$

219 so we obtain the tensors $\tilde{\mathcal{G}}_r \stackrel{\text{def}}{=} \mathcal{G}_r \cdot_1 \mathbf{A}_r$ (indeed, the horizontal slices of $\mathcal{T} \cdot_2 \mathbf{B}^{-1} \cdot_3 \mathbf{C}^{-1}$
 220 are block-diagonal matrices and the k th horizontal slice of $\tilde{\mathcal{G}}_r$ is just the r th block
 221 of the k th horizontal slice of $\mathcal{T} \cdot_2 \mathbf{B}^{-1} \cdot_3 \mathbf{C}^{-1}$). It is clear that \mathcal{G}_r and \mathbf{A}_r can be
 222 recovered from $\tilde{\mathcal{G}}_r$, again up to the intrinsic indeterminacies. For example, one can
 223 compute the SVD $\mathbf{U} \Sigma \mathbf{V}^H = \tilde{\mathbf{G}}_{r[2,3:1]}$, take $\mathbf{A}_r = \mathbf{U}(:, 1 : \mu_r)$ and set $\mathcal{G}_r = \tilde{\mathcal{G}}_r \cdot_1 \mathbf{A}_r^H$.
 224 Consequently, by doing this for all R terms we obtain the BTD (3).

¹In the following, we use the term "compression" to refer to the MLSVD-based compression.

²Step 1 in Proof of Theorem 4.4 in Appendix A ensures that a generic \mathbf{f} will yield a nonsingular matrix \mathbf{T}_1 .

225 We conclude by mentioning that, instead of working with the above block-diagonalization
 226 of $\mathbf{T}_2 \mathbf{T}_1^{-1}$, one can also use a block-diagonalization of the matrix pencil $(\mathbf{T}_1, \mathbf{T}_2)$ which
 227 is to be preferred numerically as it avoids the inverse of \mathbf{T}_1 . The algebraic computation
 228 discussed here generalizes the GEVD based computation of the CPD used in [38]. Just
 229 as the CPD in [38] may be seen as an extension of GEVD to more than two matrices,
 230 the considered BTD here may be seen as an extension of block-diagonalization to more
 231 than two matrices. Furthermore, one can use optimization-based approaches [29] to
 232 compute the BTD or, if necessary, refine the results obtained from algebraic methods.
 233 This is, again, a similar situation as for the CPD in [38].

234 **3.2. The Macaulay null space.** Our approach exploits the Vandermonde
 235 structure in the null space of a Macaulay matrix of sufficiently high degree.

236 **3.2.1. Simple roots.**

237 **DEFINITION 3.2.** [15, p. 263] Let $f_i \in \mathbb{C}_{d_i}^n$, $i = 1 : s$, be s polynomials of degree
 238 d_i in n variables x_1, \dots, x_n , then the Macaulay matrix $\mathbf{M}(d)$ of degree d contains as
 239 its rows the coefficients of

$$240 \quad \mathbf{M}(d) = \begin{pmatrix} f_1 \\ x_1 f_1 \\ \vdots \\ x_n^{d-d_1} f_1 \\ f_2 \\ x_1 f_2 \\ \vdots \\ x_n^{d-d_s} f_s \end{pmatrix} \in \mathbb{C}^{\sum_{i=1}^s q(d-d_i) \times q(d)}$$

241 where each polynomial f_i , $i = 1 : s$, is multiplied with all possible monomials \mathbf{x}^α ,
 242 $\deg(\mathbf{x}^\alpha) = 0 : d - d_i \in \mathbb{N}$.

243 If the system (1) has only simple roots, the null space of $\mathbf{M}(d)$ constructed at a de-
 244 gree d greater than or equal to the so-called degree of regularity d^* , is m -dimensional;
 245 it is generated by m multivariate Vandermonde vectors

$$246 \quad (8) \quad \mathbf{v}_k(d) = \left(1 \quad x_1^{(k)} \quad x_2^{(k)} \quad \dots \quad x_1^{(k)2} \quad x_1^{(k)} x_2^{(k)} \quad \dots \quad x_{n-1}^{(k)} x_n^{(k)d-1} \quad x_n^{(k)d} \right)^T \in \mathbb{C}^{q(d)},$$

247 where $x_j^{(k)}$ denotes the j th coordinate of the k th root, $k = 1 : m$, $j = 1 : n$. For more
 248 background, see [38].

249 **3.2.2. The multiplicity structure of a root.** Let the fixed set of m points
 250 $\mathcal{Z} = \{\mathbf{z}_k\}_{k=1}^m \subset \mathbb{C}^n$ represent the solution set of the system (1). The system is then
 251 defined by a basis \mathcal{F} for the polynomial ideal $\mathcal{I} \subset \mathbb{C}^n$ of all polynomials that attain
 252 zero on the set \mathcal{Z} . The set of residue classes $[r] = \{r' \in \mathbb{C}^n \mid r - r' \in \mathcal{I}\}$ is a quotient
 253 ring $\mathbb{C}^n / \mathcal{I}$ induced by the polynomial ideal \mathcal{I} .

254 If all elements of \mathcal{Z} occur with multiplicity 1, i.e. if the system defined by \mathcal{F} has
 255 only simple roots, then the characterization of the residue classes is straightforward.
 256 We have that a polynomial $g \in \mathcal{I} \Leftrightarrow g(\mathbf{z}_k) = 0$ for all k . Further, $g \in [r] \Leftrightarrow g - r \in$
 257 $\mathcal{I} \Leftrightarrow (g - r)(\mathbf{z}_k) = 0$ for all k . Any residue class is completely characterized by the
 258 value evaluations of its members on the set of m points \mathcal{Z} , and $\dim \mathbb{C}^n / \mathcal{I} = m$.

259 However, if one or more of the elements of \mathcal{Z} occur with multiplicity greater than
 260 1, i.e. if the system defined by \mathcal{F} has coinciding roots, things become more subtle.

261 Say there are $m_0 < m$ disjoint roots $\mathcal{Z}_0 = \{\mathbf{z}_k\}_{k=1}^{m_0} \subset \mathcal{Z}$, occurring with multiplicity
 262 μ_k in \mathcal{Z} , such that $\sum_{k=1}^{m_0} \mu_k = m$. One can show that the dimension of $\mathcal{C}^n/\mathcal{I}$ remains
 263 m but that $g(\mathbf{z}_k) = 0$ for all $k = 1 : m_0$ is no longer sufficient for $g \in \mathcal{I}$ [35, pp.
 264 91–92]. For a concise characterization of the residue classes, we introduce differential
 265 functionals. Differential functionals act on a polynomial $f \in \mathcal{C}^n$ first by differentiation
 266 (\cdot) and then by evaluation $[\cdot]$.

267 DEFINITION 3.3 (differential functional). [35, p. 90] Let $\mathbf{z} \in \mathbb{C}^n$ and $f \in \mathcal{C}^n$, then
 268 a differential functional monomial is defined by

$$269 \quad \partial_{\mathbf{j}}[\mathbf{z}](f) = \partial_{j_1 \dots j_n}[\mathbf{z}](f) = \frac{1}{j_1! \dots j_n!} \left(\frac{\partial^{\sum_{i=1}^n j_i}}{\partial x_1^{j_1} \dots \partial x_n^{j_n}} f \right) (\mathbf{z})$$

270 where $\mathbf{j} = (j_1 \dots j_n)^T \in \mathbb{N}^n$. Any linear combination $\sum_{\mathbf{j}} \beta_{\mathbf{j}} \partial_{\mathbf{j}}[\mathbf{z}](f)$ with $\beta_{\mathbf{j}} \in \mathbb{C}$ of
 271 differential functional monomials $\partial_{\mathbf{j}}[\mathbf{z}](f)$ is a differential functional.

272 The order of the differential functional monomial $\partial_{\mathbf{j}}$ is defined as $o(\partial_{\mathbf{j}}) = |\mathbf{j}| =$
 273 $\sum_{i=1}^n j_i$ [6, p. 2145]. The order of a linear combination is the order of the highest
 274 order differential functional monomial in that linear combination.

275 Let us turn back to the characterization of the residue classes. Gröbner Duality
 276 formulates a sufficient condition for $g \in \mathcal{I}$ in terms of differential functionals.

277 DEFINITION 3.4 (Gröbner Duality). [20, p. 174-178] Let the system of polynomi-
 278 als defined by a basis \mathcal{F} for the ideal \mathcal{I} have $m_0 \leq m$ disjoint roots. Then \mathbf{z}_k is a root
 279 of the system with multiplicity μ_k iff μ_k linearly independent differential functionals
 280 $\sum_{\mathbf{j}} \beta_{\mathbf{j}} \partial_{\mathbf{j}}[\mathbf{z}_k](g)$ vanish for $g \in \mathcal{I}$.

281 Hence, given the fixed set \mathcal{Z} , Gröbner Duality states that a sufficient condition for
 282 $g \in \mathcal{I}$ is that $c_{kl}(g) = 0$ for all $k = 1 : m_0$, where, for the k th root (with multiplicity
 283 μ_k), we need to consider $c_{k0} = \partial_0[\mathbf{z}_k]$ of order 0 and $\mu_k - 1$ differential functionals
 284 c_{kl} of order greater than 0. The collection $\mathcal{D}[\mathbf{z}_k](\mathcal{F}) = \{c_{kl} \mid \forall f \in \mathcal{F} : c_{kl}(f) = 0\}$
 285 containing these differential functionals is referred to as the multiplicity structure of
 286 the root \mathbf{z}_k . The dimension of \mathcal{D} equals μ_k and the depth δ_k of \mathcal{D} is defined as the
 287 highest order of the differential functionals in \mathcal{D} .³ Summarizing, a residue class is
 288 now completely characterized by value and derivative evaluations contained in all the
 289 $\mathcal{D}[\mathbf{z}_k]$ together, $k = 1 : m_0$.

290 Several algorithms to compute the multiplicity structure have been proposed in
 291 the literature [26, 7, 41, 6]. One such algorithm is Macaulay’s algorithm [26]. The idea
 292 of Macaulay’s approach is to compute \mathcal{D} by computing the null space of Macaulay-
 293 like matrices at increasing degrees. Indeed, as already mentioned in [38], the m -
 294 dimensional null space of $\mathbf{M}(d)$ at a degree $d \geq d^*$ is isomorphic with the set of all
 295 residue classes $\mathcal{C}_d^n/\mathcal{I}$.

296 In the remainder of this paper, we will write $\partial_{\mathbf{j}}[\mathbf{v}]$ or, more generally, $c[\mathbf{v}]$ for
 297 a differential functional that acts on a multivariate Vandermonde vector \mathbf{v} first by
 298 differentiation and then by evaluation of its entries.

299 EXAMPLE 3.5. [16, Example 7] Consider the system of $s = 2$ polynomial equations
 300 in $n = 2$ variables

$$301 \quad \begin{cases} f_1(x_1, x_2) = (x_2 - 2)^2 = 0 \\ f_2(x_1, x_2) = (x_1 - x_2 + 1)^2 = 0 \end{cases}$$

³The differential functionals constitute a basis for the so-called dual space of the ideal \mathcal{I} and the dimension of \mathcal{D} is the dimension of the dual subspace spanned by the elements of \mathcal{D} — see also Definition B.1.

302 where $d^{(1)} = d^{(2)} = 2$, $d^* = 2 + 2 - 2 = 2$ and $m = 2 \cdot 2 = 4$, but $m_0 = 1$. The system
 303 has $m_0 = 1$ disjoint root $\mathbf{x}^{(1)} = \begin{pmatrix} x_1^{(1)} & x_2^{(1)} \end{pmatrix}^T = (1 \ 2)^T$ with multiplicity $\mu_1 = 4$. It
 304 can be verified that a basis for the $(m = 4)$ -dimensional null space of

$$305 \quad \mathbf{M}(d) = \begin{pmatrix} 4 & 0 & -4 & 0 & 0 & 1 \\ 1 & 2 & -2 & 1 & -2 & 1 \end{pmatrix}$$

306 at $d = d^*$ is given by the multivariate Vandermonde vector $c_{10}[\mathbf{v}(d)] = \partial_0[\mathbf{v}(2)] =$
 307 $\mathbf{v}(2)$, the “first-order derivative vectors” $c_{11}[\mathbf{v}(2)] = \partial_{10}[\mathbf{v}(2)]$
 308 and $c_{12}[\mathbf{v}(2)] = \partial_{01}[\mathbf{v}(2)]$ and the linear combination of “second-order derivative
 309 vectors” $c_{13}[\mathbf{v}(2)] = (2\partial_{20} + \partial_{11})[\mathbf{v}(2)]$ (In the notation of [Definition 3.3](#), we have
 310 $\beta_{00} = \beta_{10} = \beta_{01} = \beta_{11} = 1$ and $\beta_{20} = 2$). This basis⁴ is stacked in a matrix that will
 311 be called confluent multivariate Vandermonde in [subsection 3.3.2](#):

$$312 \quad (9) \quad \tilde{\mathbf{V}}(2) \stackrel{\text{def}}{=} \begin{pmatrix} c_{10}[\mathbf{v}(2)] & c_{11}[\mathbf{v}(2)] & c_{12}[\mathbf{v}(2)] & c_{13}[\mathbf{v}(2)] \\ \partial_{00}[\mathbf{v}(2)] & \partial_{10}[\mathbf{v}(2)] & \partial_{01}[\mathbf{v}(2)] & (2\partial_{20} + \partial_{11})[\mathbf{v}(2)] \end{pmatrix}$$

$$313 \quad = \begin{pmatrix} 1 & 0 & 0 & 0 \\ x_1^{(1)} & 1 & 0 & 0 \\ x_2^{(1)} & 0 & 1 & 0 \\ x_1^{(1)2} & 2x_1^{(1)} & 0 & 2 \\ x_1^{(1)}x_2^{(1)} & x_2^{(1)} & x_1^{(1)} & 1 \\ x_2^{(1)2} & 0 & 2x_2^{(1)} & 0 \end{pmatrix}.$$

$$314$$

315 The depth δ_1 of $\mathcal{D}[\mathbf{x}^{(1)}]$ is equal to the order of $c_{13}[\mathbf{v}(2)]$: $\delta_1 = 2$.

316 **3.3. Vandermonde matrices.** In what follows matrices having Vandermonde
 317 structure will play an important role, so we shall recall some properties here for both
 318 uni- and multivariate Vandermonde matrices.

319 **3.3.1. Vandermonde matrices with distinct generators.** We consider uni-
 320 variate Vandermonde matrices $\mathbf{V}^{(j)}(d) \in \mathbb{C}^{(d+1) \times m}$ generated by the j th coordinate
 321 of the m roots of (1), denoted by $\{x_j^{(k)}\}$, $k = 1 : m$, $j = 1 : n$:

$$322 \quad \mathbf{V}^{(j)}(d) = \left(\mathbf{v}_1^{(j)}(d), \dots, \mathbf{v}_m^{(j)}(d) \right), \quad \mathbf{v}_k^{(j)}(d) = \left(1, x_j^{(k)}, x_j^{(k)2}, \dots, x_j^{(k)d} \right)^T.$$

323 The univariate Vandermonde matrix $\mathbf{V}^{(j)}(d)$ has full column rank if all *generators*
 324 $x_j^{(k)}$ are distinct, $k = 1 : m$. We will make use of *spatial smoothing* [30]. This means
 325 that if we take the outer product of subvectors $\mathbf{v}_k^{(j)}(1 : L) \cdot \mathbf{v}_k^{(j)}(1 : d - L + 2)^T$, the

⁴Like the multivariate Vandermonde basis in the case of simple roots, this confluent multivariate Vandermonde basis is only one possible basis for the Macaulay null space. In practice, it is a numerical basis that will be computed. Both are related by an a priori unknown basis transformation — see (17).

326 result is a rank-1 Hankel matrix:
327

$$\begin{aligned}
328 \quad (10) \quad \mathbf{v}_k^{(j)}(1:L) \otimes \mathbf{v}_k^{(j)}(1:d-L+2) &= \begin{pmatrix} 1 \\ x_j^{(k)} \\ \vdots \\ x_j^{(k)(L-1)} \end{pmatrix} \otimes \begin{pmatrix} 1 \\ x_j^{(k)} \\ x_j^{(k)2} \\ \vdots \\ x_j^{(k)(d-L+1)} \end{pmatrix} = \\
329 \quad \text{vec} \left(\begin{pmatrix} 1 \\ x_j^{(k)} \\ \vdots \\ x_j^{(k)(L-1)} \end{pmatrix} \begin{pmatrix} 1 \\ x_j^{(k)} \\ x_j^{(k)2} \\ \vdots \\ x_j^{(k)(d-L+1)} \end{pmatrix}^T \right) & \\
330 \quad = \text{vec} \underbrace{\begin{pmatrix} 1 & x_j^{(k)} & \dots & x_j^{(k)(d-L+1)} \\ x_j^{(k)} & x_j^{(k)2} & \dots & x_j^{(k)(d-L+2)} \\ \vdots & \vdots & & \vdots \\ x_j^{(k)(L-1)} & x_j^{(k)L} & \dots & x_j^{(k)d} \end{pmatrix}}_{=\mathbf{H}_k}. &
\end{aligned}$$

331

332 The structure is called (*multiplicative*) *shift-invariance*, referring to the shifting of
333 entries when the power of $x_j^{(k)}$ is raised. In [38] we have used the variant for $L = 2$.
334 In Part II we will use the variant for $L > 2$.

335 For multivariate generators $\{(x_1^{(k)}, \dots, x_n^{(k)})\}$, $k = 1 : m$, we define multivariate
336 Vandermonde matrices of degree d as

$$337 \quad (11) \quad \mathbf{V}(d) = (\mathbf{v}_1(d) \quad \dots \quad \mathbf{v}_m(d)) \in \mathbb{C}^{q(d) \times m},$$

338 where each column $\mathbf{v}_k(d)$ is in the multivariate Vandermonde form of (8). Multi-
339 variate Vandermonde matrices exhibit a multiplicative shift structure in each vari-
340 able x_j . More precisely, a multivariate Vandermonde matrix consists of the rows
341 of the Khatri–Rao product of the n univariate Vandermonde matrices $\mathbf{V}^{(j)}(d)$ that
342 are associated with the monomials up to degree d . Formally, we have $\mathbf{V}(d) =$
343 $\mathbf{S}_{(d+1)^n \rightarrow q(d)}(\mathbf{V}^{(1)}(d) \odot \dots \odot \mathbf{V}^{(n)}(d))$, where $\mathbf{V}^{(j)}(d) \in \mathbb{C}^{(d+1) \times m}$, $j = 1 : n$, are
344 univariate Vandermonde matrices of degree d constructed from the j th coordinate
345 of the m roots and $\mathbf{S}_{(d+1)^n \rightarrow q(d)} \in \mathbb{R}^{q(d) \times (d+1)^n}$ eliminates all duplicate rows in the
346 Khatri–Rao products, truncates the monomials of degree higher than d , and reorders
347 the remaining $q(d)$ monomials according to the chosen monomial order. The matrix
348 $\mathbf{S}_{(d+1)^n \rightarrow q(d)}$ can be constructed by n -fold composition of the “elimination matrices”
349 in [27]. See [38] for more details, where the n -fold multiplicative shift structure was
350 used to connect the null space of the Macaulay matrix to CPD.

351 **3.3.2. Confluent Vandermonde matrices.** If m_0 distinct univariate genera-
352 tors $x_j^{(k)}$ occur each with multiplicities $\mu_k \geq 1$, and $m = \sum_{k=1}^{m_0} \mu_k$ is the total number
353 of generators, the associated univariate Vandermonde matrix $\mathbf{V}^{(j)}(d)$ set up in a naive
354 way would have identical columns and, hence, be rank deficient. Confluent univariate
355 Vandermonde matrices

$$356 \quad \tilde{\mathbf{V}}^{(j)}(d) = \left(\tilde{\mathbf{V}}_1^{(j)}(d), \dots, \tilde{\mathbf{V}}_{m_0}^{(j)}(d) \right)$$

357 capture the multiplicities by including “derivative vectors” in submatrices of the form

358
$$\tilde{\mathbf{V}}_k^{(j)}(d) = \left(\mathbf{v}_k^{(j)}(d) \quad \frac{d}{dx_j}[\mathbf{v}_k^{(j)}(d)] \quad \cdots \quad \frac{1}{(\mu_k-1)!} \frac{d^{\mu_k-1}}{dx_j^{\mu_k-1}}[\mathbf{v}_k^{(j)}(d)] \right) \in \mathbb{C}^{(d+1) \times \mu_k}, \quad k = 1 : m_0$$

359 with Vandermonde vectors $\mathbf{v}_k^{(j)}(d)$ as in [subsection 3.3.1](#), see, e.g., [22, 10]. Only the
 360 first column $\mathbf{v}_k^{(j)}(d)$ of $\tilde{\mathbf{V}}_k^{(j)}(d)$ enjoys the multiplicative shift-invariance mentioned
 361 in [subsection 3.3.1](#). The submatrices $\tilde{\mathbf{V}}_k^{(j)}(d)$ are for $I, I - L + 1 \geq \mu_k$ related to a
 362 rank- μ_k Hankel matrix via $\tilde{\mathbf{H}}_k = \tilde{\mathbf{V}}_k^{(j)}(d)(1 : L, :) \cdot \mathbf{D}_k^{(j)} \cdot \tilde{\mathbf{V}}_k^{(j)}(d)(1 : I - L, :)$, where

363
$$\mathbf{D}_k^{(j)} = \begin{pmatrix} 1 & x_j^{(k)} & x_j^{(k)2} & \cdots & x_j^{(k)(\mu_k-1)} \\ x_j^{(k)} & x_j^{(k)2} & x_j^{(k)3} & \cdots & 0 \\ x_j^{(k)2} & x_j^{(k)3} & x_j^{(k)4} & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ x_j^{(k)(\mu_k-1)} & 0 & \cdots & \cdots & 0 \end{pmatrix} \in \mathbb{C}^{\mu_k \times \mu_k}$$

364 is nonsingular and Hankel, see, e.g., [3, 10]. This can be seen as block generalization
 365 of the spatial smoothing structure in (10).

366 For the multivariate case, the multiplicity structure of a multiple root defined in
 367 [subsection 3.2.2](#) gives rise to a generalization of multivariate Vandermonde matrices
 368 of the form

369 (12)
$$\tilde{\mathbf{V}}(d) = (\tilde{\mathbf{V}}_1(d) \quad \cdots \quad \tilde{\mathbf{V}}_{m_0}(d)) \in \mathbb{C}^{q(d) \times m},$$

370 in which

371
$$\tilde{\mathbf{V}}_k(d) = (\tilde{\mathbf{v}}_{k,0}(d) \quad \tilde{\mathbf{v}}_{k,1}(d) \quad \cdots \quad \tilde{\mathbf{v}}_{k,\mu_k-1}(d))$$

 372
$$= (c_{k0}[\mathbf{v}_k(d)] \quad c_{k1}[\mathbf{v}_k(d)] \quad \cdots \quad c_{k,\mu_k-1}[\mathbf{v}_k(d)]) \in \mathbb{C}^{q(d) \times \mu_k},$$

373 for $k = 1 : m_0$, where $c_{k,l}$ are the differential functionals from the multiplicity structure
 374 $\mathcal{D}[\mathbf{z}_k](\mathcal{F})$. We shall refer to (12) as confluent multivariate Vandermonde matrices, see
 375 also [17]. Each submatrix $\tilde{\mathbf{V}}_k(d) \in \mathbb{C}^{q(d) \times \mu_k}$ reflects the multiplicity structure $\mathcal{D}[\mathbf{z}_k]$
 376 of the k th root. The depth δ_k of $\mathcal{D}[\mathbf{z}_k]$ is the highest order of the corresponding $c_{k,\cdot}$
 377 in $\tilde{\mathbf{V}}_k(d)$. Only the first column $c_{k0}[\mathbf{v}_k(d)] = \tilde{\mathbf{v}}_{k,0}(d) = \mathbf{v}_k(d)$ in each submatrix has
 378 the shift-invariance property. The confluent multivariate Vandermonde matrix $\tilde{\mathbf{V}}(d)$
 379 is of full column rank m and constitutes a basis for the m -dimensional nullspace of
 380 $\mathbf{M}(d)$ for $d \geq d^*$.

381 **4. From the Macaulay null space to BTD.** Here we unravel the BTD struc-
 382 ture in the Macaulay null space $\mathbf{K}(d)$, $d \geq d^*$. For the sake of presentation and
 383 simplicity, we mainly restrict ourselves to the affine case, but generalizations to the
 384 projective case follow by interpreting Vandermonde vectors $\mathbf{v}(d)$ as

385 (13)
$$\mathbf{v}^h(d) = (x_0^d \quad x_0^{d-1}x_1 \quad \cdots \quad x_0^{d-2}x_1^2 \quad x_0^{d-2}x_1x_2 \quad \cdots \quad x_n^d)^T \in \mathbb{C}^{q(d)},$$

386 and consequently using $\mathbf{j} \in \mathbb{N}^{n+1}$ in the differential functionals (i.e., also include
 387 partial derivatives in x_0), see [15]. Details on a special treatment of roots at infinity
 388 ($x_0 = 0$) are given when necessary.

389 **4.1. CPD and simple roots.** [38] jointly exploits the multiplicative shift in-
 390 variance in each variable x_j in the null space of the Macaulay matrix of a system
 391 with only simple roots. The null space admits a multivariate Vandermonde basis,
 392 corresponding to the columns of $\mathbf{V}(d) \in \mathbb{C}^{q(d) \times m}$. This multivariate Vandermonde
 393 basis is not readily available. What we can find is a numerical basis, which we stack
 394 in $\mathbf{K}(d) \in \mathbb{C}^{q(d) \times m}$. Obviously, we have $\mathbf{K}(d) = \mathbf{V}(d)\mathbf{C}(d)^T$ with an invertible basis
 395 transformation matrix $\mathbf{C}(d) \in \mathbb{C}^{m \times m}$. Exploiting the structure results in the following
 396 third-order tensor CPD [38]:

$$\begin{aligned}
 397 \quad \mathbf{Y}_{[1,2;3]} &\stackrel{\text{def}}{=} \begin{pmatrix} \bar{\mathbf{S}}^{(0)}(d-1) \cdot \mathbf{K}(d) \\ \bar{\mathbf{S}}^{(1)}(d-1) \cdot \mathbf{K}(d) \\ \vdots \\ \bar{\mathbf{S}}^{(n)}(d-1) \cdot \mathbf{K}(d) \end{pmatrix} \\
 398 \quad (14) \quad &= \left(\begin{pmatrix} 1 & 1 & \dots & 1 \\ x_1^{(1)} & x_1^{(2)} & \dots & x_1^{(m)} \\ \vdots & \vdots & & \vdots \\ x_n^{(1)} & x_n^{(2)} & \dots & x_n^{(m)} \end{pmatrix} \odot \mathbf{B}(d-1) \right) \mathbf{C}(d)^T
 \end{aligned}$$

$$\begin{aligned}
 399 \quad &= (\mathbf{V}(1) \odot \mathbf{V}(d-1)) \cdot \mathbf{C}(d)^T \in \mathbb{C}^{((n+1) \cdot q(d-1)) \times m}, \\
 400 \quad (15) \quad &\text{or } \mathcal{Y} = \llbracket \mathbf{V}(1), \mathbf{V}(d-1), \mathbf{C}(d) \rrbracket \in \mathbb{C}^{(n+1) \times q(d-1) \times m},
 \end{aligned}$$

401 where $\bar{\mathbf{S}}^{(j)}(d-1)$ selects all rows of $\mathbf{K}(d)$ onto which the rows of $\mathbf{K}(d)$, associated with
 402 monomials of degree at most $d-1$ in x_j , are mapped after multiplication with x_j . In
 403 the projective case the CPD in (14) is constructed using multivariate Vandermonde
 404 matrices $\mathbf{V}^h(1)$, $\mathbf{V}^h(d-1)$ of the form $\mathbf{V}^h(d) = (\mathbf{v}_1^h(d) \ \dots \ \mathbf{v}_m^h(d)) \in \mathbb{C}^{q(d) \times m}$
 405 with $\mathbf{v}_k^h(d)$ as in (13) and containing the k th root $(x_0^{(k)} \ x_1^{(k)} \ \dots \ x_n^{(k)})^T$ in the
 406 projective interpretation.

407 **4.2. BTD and multiple roots.** Let now $\tilde{\mathbf{V}}(d)$ as in (12) denote a confluent
 408 multivariate Vandermonde (“multivariate Vandermonde plus derivative”) basis for the
 409 null space of the Macaulay matrix of a system with multiple roots:

$$410 \quad (16) \quad \mathbf{M}(d) \cdot \tilde{\mathbf{V}}_k(d) = \mathbf{M}(d) \cdot (c_{k0}[\mathbf{v}(d)] \ \dots \ c_{k,\mu_k-1}[\mathbf{v}(d)]) = \mathbf{0}, \quad k = 1 : m_0.$$

411 The multiplicity structure in (16) is not unique [15] (unless $\mu_k = 1$ for all k). Indeed,
 412 multiplying both sides in (16) with a nonsingular transformation matrix $\mathbf{T} \in \mathbb{C}^{\mu_k \times \mu_k}$
 413 yields the equally valid relation

$$414 \quad (17) \quad \mathbf{M}(d) \tilde{\mathbf{V}}_k(d) \mathbf{T} = \mathbf{M}(d) (\tilde{\mathbf{V}}_k(d) \mathbf{T}) = \mathbf{0}.$$

415 In the following we partition the invertible transformation matrix $\mathbf{C}(d)$ so that it
 416 matches the partition in (12):

$$417 \quad \mathbf{C}(d) = (\mathbf{C}_1(d) \ \dots \ \mathbf{C}_{m_0}(d)) \in \mathbb{C}^{m \times m}.$$

418 We emphasize that $\tilde{\mathbf{V}}_k(d)$ ($\tilde{\mathbf{V}}(d)$) is *not* multivariate Vandermonde and that the newly
 419 introduced columns in $\tilde{\mathbf{V}}_k(d)$ (in $\tilde{\mathbf{V}}(d)$) do *not* exhibit shift invariance as discussed
 420 in [38, Section 3.3]. Hence, we cannot implement *simple* spatial smoothing to exploit
 421 this shift invariance and we do not obtain the CPD in (2) anymore.

Fig. 2: Schematic of the BTD (19) for $\mathcal{Y} \in \mathbb{C}^{q(d^{(1)}) \times q(d^{(2)}) \times m}$ for a system of $s = 2$ polynomial equations in $n = 2$ unknowns. Counting multiplicities, the number of roots $m = 4$. The number of distinct roots $m_0 = 3$. The first two roots are isolated ($\mu_1 = \mu_2 = 1$). The third root has multiplicity $\mu_3 = 2$ with depth $\delta_3 = 1$. The degrees in [Theorem 4.2](#) are chosen as $d^{(1)} = 1$ and $d^{(2)} = 2$ such that $d^{(1)} + d^{(2)} = 3 \geq d^* = 2$.

422 **EXAMPLE 4.1.** Consider again the system in [Example 3.5](#). Since it has $m_0 = 1$
 423 distinct roots, we omit the subscript indicating the numbering of the distinct roots
 424 in (12) and use $\tilde{\mathbf{V}}(2) = \tilde{\mathbf{V}}_1(2)$ as in (9). The first column of $\tilde{\mathbf{V}}(2)$ enjoys shift-
 425 invariance:

$$426 \quad \tilde{\mathbf{V}}([1\ 2\ 3], 1) \cdot x_1^{(1)} = \begin{pmatrix} 1 \\ x_1^{(1)} \\ x_2^{(1)} \end{pmatrix} \cdot x_1^{(1)} = \begin{pmatrix} x_1^{(1)} \\ x_1^{(1)2} \\ x_1^{(1)}x_2^{(1)} \end{pmatrix} = \tilde{\mathbf{V}}([2\ 4\ 5], 1).$$

427 Similarly, $\tilde{\mathbf{V}}([1\ 2\ 3], 1) \cdot x_2^{(1)} = \tilde{\mathbf{V}}([3\ 5\ 6], 1)$. However, the other columns do not ex-
 428 hibit this shift invariance property. For instance, for the second column $(\tilde{\mathbf{V}}(2))_2 =$
 429 $\partial_{10}[\mathbf{v}(2)]$ we have:

$$430 \quad \tilde{\mathbf{V}}([1\ 2\ 3], 2) \cdot x_1^{(1)} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \cdot x_1^{(1)} = \begin{pmatrix} 0 \\ x_1^{(1)} \\ 0 \end{pmatrix} \neq \begin{pmatrix} 1 \\ 2x_1^{(1)} \\ x_2^{(1)} \end{pmatrix} = \tilde{\mathbf{V}}([2\ 4\ 5], 2).$$

431

432 Nonetheless, we can formulate a BTD for \mathcal{Y} using a more general row selection
 433 in the confluent multivariate Vandermonde null space of the Macaulay matrix. [The-](#)
 434 [orem 4.2](#) gives this decomposition and its derivation is given in [Appendix B](#).

435 Let us already give that [Example 4.7](#) at the end of this section clarifies the up-
 436 coming insights on the well-known univariate playground.

437 **THEOREM 4.2.** Let the system of polynomials \mathcal{F} in n (affine) variables x_1, \dots, x_n
 438 have $m_0 \leq m$ disjoint roots with multiplicity $\mu_k, k = 1 : m_0$. Assume $d = d^{(1)} + d^{(2)} \geq$

471 **Theorem 4.2** gives only the BTD (19) but not its uniqueness nor a way to compute
 472 it algebraically. However, if it is unique, it could already be computed by means of
 473 optimization based algorithms [29].

474 **4.3. Uniqueness and algebraic computation of the BTD.** The following
 475 **Theorem 4.4** gives conditions that ensure uniqueness of (19) and, furthermore, enable
 476 an algebraic computation of the factor matrices using block-diagonalization of certain
 477 matrices. We will see that for this to work, a higher Macaulay degree d and further as-
 478 sumptions on $d^{(1)}, d^{(2)}$ might be necessary than only for constructing (19). Moreover,
 479 **Theorem 4.4** forms the counterpart to [38, Theorem 6.1] which established the unique-
 480 ness of the CPD (15) and the ability to compute it via eigenvalue decompositions in
 481 the case of only simple roots.

482 **THEOREM 4.4.** Define $\mathbf{A} \stackrel{\text{def}}{=} (\mathbf{A}_1 \ \dots \ \mathbf{A}_{m_0}) \in \mathbb{C}^{q(d^{(1)}) \times m}$,
 483 $\mathbf{B} \stackrel{\text{def}}{=} (\mathbf{B}_1 \ \dots \ \mathbf{B}_{m_0}) \in \mathbb{C}^{q(d^{(2)}) \times m}$ and let $\mathbf{C} \in \mathbb{C}^{m \times m}$ be the invertible basis trans-
 484 formation from above. Let $d = d^{(1)} + d^{(2)}$ where $d^{(1)}, d^{(2)}$ satisfy

- 485 1. $d^{(2)} \geq d^*$,
- 486 2. $d^{(1)} \geq \max\{1, \max_k \delta_k\}$.

487 Then the BTD (19) is unique.

488 *Proof.* The condition $d^{(1)} \geq \max\{1, \max_k \delta_k\}$ ensures that all individual blocks
 489 $\mathbf{A}_r = \tilde{\mathbf{V}}_r(d^{(1)})$, $r = 1 : m_0$ have full column rank, so (19) is a decomposition into
 490 a sum of multilinear rank- (μ_r, μ_r, μ_r) terms. To prove uniqueness we show that the
 491 assumptions in **Theorem 3.1** hold for $R = m_0$, $I_1 = q(d^{(1)})$, $I_2 = q(d^{(2)})$, and $I_3 = m$.
 492 By **Theorem 4.2**, it is sufficient to show that assumptions (5) and (6) hold. Note that
 493 both conditions always imply $d \geq d^* + 1$. For $d \geq d^*$ we have that $\dim \text{null}(\mathbf{M}(d)) = m$
 494 and that the numerical basis $\mathbf{K}(d) \in \mathbb{C}^{q(d) \times m}$ has full column rank $r_{\mathbf{K}(d)} = m$. Thus,
 495 \mathbf{C} has also full column rank. Since $\mathbf{B} = \tilde{\mathbf{V}}(d^{(2)})$ and $r_{\tilde{\mathbf{V}}(d^{(2)})} = m$ for $d^{(2)} \geq d^*$ [15],
 496 the second condition ensures full column rank of \mathbf{B} . Finally, since the first columns
 497 of the \mathbf{A}_k , $k = 1 : m_0$ are genuine multivariate Vandermonde vectors associated to
 498 the m_0 distinct roots, (6) is always satisfied for $d^{(1)} \geq 1$. \square

499 **EXAMPLE 4.5.** We revisit **Example 3.5** (see also **Example 4.3**) with $n = s = 2$,
 500 initial degree $d_0 = 2$ so that $d_* = d_0 \cdot n - n = 2$, $m_0 = 1 < m = d_0^2 = 4$, $\mu_1 = 4$,
 501 $\delta_1 = 2$. Taking $d^{(2)} = 2$ and $d^{(1)} = 2$ as we did before satisfies the conditions 1. and
 502 2. of **Theorem 4.4**.

503 Under the conditions of **Theorem 4.4**, the BTD of \mathcal{Y} and its factor matrices can
 504 be computed algebraically by following the steps outlined in **subsection 3.1.2**. Similar
 505 as in [38, Algorithm 1], we start from a compressed version $\mathcal{Y}_c \in \mathbb{C}^{q(d^{(1)}) \times m \times m}$ of \mathcal{Y} .

506 The algebraic method in **subsection 3.1.2** requires a block-diagonal decomposi-
 507 tion of $\mathbf{T}_2 \mathbf{T}_1^{-1}$, where $\mathbf{T}_1 \stackrel{\text{def}}{=} \mathcal{Y}_c \cdot_1 \mathbf{f}^T$, $\mathbf{T}_2 \stackrel{\text{def}}{=} \mathcal{Y}_c \cdot_1 \mathbf{g}^T \in \mathbb{C}^{m \times m}$ are generic linear
 508 combinations of the horizontal slices $\mathcal{Y}_c(i, :, :)$ with $\mathbf{f}, \mathbf{g} \in \mathbb{C}^{I_1}$. In practice, one would
 509 compute this block-diagonal decomposition of $\mathbf{T}_2 \mathbf{T}_1^{-1}$ from a Schur decomposition,
 510 see [19, §7.6.3], resulting in factor matrices \mathbf{A}, \mathbf{B} that are not in confluent multivariate
 511 Vandermonde form, but rather in the form $\mathbf{A} = \tilde{\mathbf{V}}(d^{(1)}) \mathbf{R}^{(1)}$, $\mathbf{B} = \tilde{\mathbf{V}}(d^{(2)}) \mathbf{R}^{(2)}$
 512 with some unknown invertible transformations $\mathbf{R}^{(1)}, \mathbf{R}^{(2)} \in \mathbb{C}^{m \times m}$. This does not
 513 immediately reveal the roots but we will see later in **section 6** how the roots and their
 514 multiplicities can nevertheless be retrieved.

515 **4.4. Connection with NPA.** Let the system of polynomials \mathcal{F} have $m_0 \leq m$
 516 disjoint roots. Consider the family of multiplication tables $\{\mathbf{A}_{x_j}\}_{j=1}^n$ where $\mathbf{A}_h \in$

517 $\mathbb{C}^{m \times m}$ represents a multiplication with the residue class $[h]$ in the m -dimensional
 518 quotient ring $\mathcal{C}^n/\mathcal{I} = \mathcal{C}^n/\langle \mathcal{F} \rangle$ associated to an arbitrary basis, e.g., the standard
 519 monomials⁵. Then the central theorem of NPA [34, Theorem 2.27] states that a μ_k -
 520 fold root $\mathbf{x}^{(k)}$ of \mathcal{F} yields eigenvalues $x_j^{(k)}$ of \mathbf{A}_{x_j} with algebraic multiplicity μ_k . There
 521 is also an associated joint invariant subspace $\text{span}(\mathbf{X}_k)$, $\mathbf{X}_k \in \mathbb{C}^{m \times \mu_k}$ such that

$$522 \quad (20) \quad \mathbf{A}_{x_j} (\mathbf{X}_1 \quad \dots \quad \mathbf{X}_{m_0}) = (\mathbf{X}_1 \quad \dots \quad \mathbf{X}_{m_0}) \begin{pmatrix} \mathbf{T}_{x_{j,1}} & & \\ & \ddots & \\ & & \mathbf{T}_{x_{j,m_0}} \end{pmatrix}$$

523 with $\mathbf{T}_{x_{j,k}} \in \mathbb{C}^{\mu_k \times \mu_k}$ upper-triangular and $x_j^{(k)}$ on the diagonal. Note that only the
 524 first columns of \mathbf{X}_k are joint eigenvectors. In case of only simple roots ($m = m_0$), this
 525 reduces to a joint diagonalization of the multiplication tables $\{\mathbf{A}_{x_j}\}_{j=1}^n$. Briefly, [38,
 526 Corollary 6.3] showed that if a tensor $\mathcal{H}(d) \in \mathbb{C}^{n \times m \times m}$ is constructed as in (14),(15)
 527 but using a column echelon echelon basis $\mathbf{H}(d)$ of $\text{null}(\mathbf{M}(d))$ as well as n proper
 528 selection matrices, associated to the m standard monomials, then the n slices of \mathcal{H}
 529 are equal to the n multiplication tables w.r.t. the normal set basis for $\mathcal{C}^n/\langle \mathcal{F} \rangle$, i.e.
 530 $\mathcal{Y}(j, :, :) = \mathbf{A}_{x_j}$, $j = 1 : n$. Corollary 4.6 extends this result to roots with multiplicities
 531 using the BTD from Theorem 4.2. The tensors \mathcal{H} in Corollary 4.6 and [38, Corollary
 532 6.3] are constructed in the same manner, but in the case of roots with multiplicities,
 533 the expressions are more involved.

534 **COROLLARY 4.6.** *Let the polynomial system \mathcal{F} have $m_0 \leq m$ disjoint affine roots*
 535 *with multiplicity $\mu_k, k = 1 : m_0$, and let $\mathbf{H}(d)$ hold the column echelon basis of*
 536 *$\text{null}(\mathbf{M}(d))$. For $d \geq d^* + 1$ let $d^{(1)}, d^{(2)}$ satisfy the conditions of Theorem 4.4.*
 537 *Consider the third-order tensor $\mathcal{H}(d)$ with matrix representation*

$$538 \quad \mathbf{H}_{[1,2;3]} = \begin{pmatrix} \hat{\mathbf{S}}^{(1)}(d-1)\mathbf{H}(d) \\ \vdots \\ \hat{\mathbf{S}}^{(n)}(d-1)\mathbf{H}(d) \end{pmatrix} \in \mathbb{C}^{(n \cdot m) \times m}$$

539 where $\hat{\mathbf{S}}^{(j)}(d-1)$ denotes the row selection matrix that selects the rows of $\mathbf{H}(d)$ onto
 540 which the m standard monomials are mapped after multiplication with x_j . Then the n
 541 slices $\{\mathcal{H}(j, :, :)\}_{j=1}^n$ of $\mathcal{H}(d)$ are equal to the n multiplication tables $\{\mathbf{A}_{x_j}\}_{j=1}^n$ w.r.t.
 542 the normal set basis for the quotient ring $\mathcal{C}^n/\langle \mathcal{F} \rangle$.

543 *Proof.* The structure in (19) does not depend on the specific choice $\mathbf{K}(d) =$
 544 $\tilde{\mathbf{V}}(d)\mathbf{C}(d)^T$ that is made for the basis of $\text{null}(\mathbf{M}(d))$, so the BTD (19) holds for
 545 $\mathbf{K}(d) = \mathbf{H}(d)$ as well. For a slice of $\mathcal{H}(d)$ we have

$$546 \quad \text{vec}(\mathcal{H}(j, :, :))^T = (\mathbf{I}_{n+1})_{j+1}^T \sum_{k=1}^{m_0} \mathbf{A}_k(1) \cdot (\mathbf{G}_k(d))_{[1;3,2]} \cdot (\mathbf{C}_k(d) \otimes \hat{\mathbf{B}}_k(d-1))^T,$$

547 where $\hat{\mathbf{B}}_k \in \mathbb{C}^{m \times \mu_k}$ contains the m rows of $\mathbf{B}_k(d-1) \in \mathbb{C}^{q(d-1) \times \mu_k}$ that correspond
 548 to the m standard monomials. At least one standard monomial has exactly degree

⁵Standard monomials refer to the monomials in the normal set basis, which relate to the Macaulay matrix as follows. If we flip the columns of $\mathbf{M}(d)$ from left to right, then the standard monomials are those monomials that correspond to the linearly dependent columns of the row echelon form of the flipped matrix [1, p. 97]. Equivalently, they correspond to the first m linearly independent rows of a multivariate Vandermonde basis for $\text{null}(\mathbf{M}(d))$ [14].

549 d^* , meaning that $d = d^* + 1$ is needed for $\mathbf{B}_k(d-1)$ to contain all the rows that
 550 correspond to the standard monomials. The multiplication with $(\mathbf{I}_{n+1})_{j+1}^T$ reveals

$$551 \quad (21) \quad \text{vec}(\mathcal{H}(j, :, :))^T = \sum_{k=1}^{m_0} \underbrace{\mathbf{A}_k(1)(j+1, :) \cdot \mathbf{G}_{k[1;3,2]}}_{=x_j^{(k)} \cdot \mathbf{G}_{k[1;3,2]}(1, :) + 1_j \cdot \mathbf{G}_{k[1;3,2]}(l+1, :)} \cdot (\mathbf{C}_k \otimes \hat{\mathbf{B}}_k)^T$$

552 where $1_j = 1$ if $\partial_{0\dots j\dots 0} = c_{kl} \in \mathcal{D}[\mathbf{x}^{(k)}]$ and 0 otherwise. Let $\tilde{\mathbf{V}}(d) = \mathbf{H}(d)\mathbf{U}$ where
 553 $\mathbf{U} \in \mathbb{C}^{m \times m}$ is an invertible transformation matrix and $\mathbf{C}^T = \mathbf{U}^{-1}$. [16, Proposition 1]
 554 shows that $(\hat{\mathbf{B}}_1 \dots \hat{\mathbf{B}}_{m_0}) = \mathbf{U}$ which, together with a matricization of (21), yields
 555

$$556 \quad \mathcal{H}(j, :, :) = \sum_{k=1}^{m_0} \hat{\mathbf{B}}_k \left(x_j^{(k)} \cdot \mathcal{G}_k(1, :, :) + 1_j \cdot \mathcal{G}_k(l+1, :, :) \right) \mathbf{C}_k^T$$

$$557 \quad = \sum_{k=1}^{m_0} \hat{\mathbf{B}}_k \underbrace{\left(x_j^{(k)} \cdot \mathbf{I}_{\mu_k} + 1_j \cdot \mathcal{G}_k(l+1, :, :) \right)}_{=\mathbf{T}_{x_j, k}} \mathbf{C}_k^T = \mathbf{U} \begin{pmatrix} \mathbf{T}_{x_j, 1} & & \mathbf{0} \\ & \ddots & \\ \mathbf{0} & & \mathbf{T}_{x_j, m_0} \end{pmatrix} \mathbf{U}^{-1}$$

558 where the right-hand side equals \mathbf{A}_{x_j} per [34, Theorem 2.27]. \square

560 We give an example that connects the insights that have emerged for multivariate
 561 polynomial equations with multiple roots to the basic univariate case.

562 **EXAMPLE 4.7.** *Consider the univariate polynomial equation*

$$563 \quad f(x) = (x - \alpha)^2 = x^2 - 2\alpha x + \alpha^2 = 0$$

564 of degree $d = 2$ and with a total number of $m = 2$ roots. The polynomial f has only
 565 $m_0 = 1$ disjoint root $x^{(1)} = \alpha$, with multiplicity $\mu_1 = 2$.

566 The Frobenius companion matrix of f ,

$$567 \quad \mathbf{A}_x = \begin{pmatrix} 0 & 1 \\ -\alpha^2 & 2\alpha \end{pmatrix},$$

568 is the matrix that describes the effect of multiplying the normal set $\{1, x\}$ with $h = x$
 569 in terms of $\{1, x\}$, i.e., in terms of [34, Theorem 2.27] it is a multiplication table.
 570 The matrix \mathbf{A}_x has the eigenvalue $x^{(1)} = \alpha$ with algebraic multiplicity $\mu_1 = 2$ but
 571 with geometric multiplicity 1. Consequently, \mathbf{A}_x cannot be diagonalized but it admits
 572 a Jordan canonical form, $\mathbf{A}_x = \mathbf{U}\mathbf{T}\mathbf{U}^{-1}$, in which

$$573 \quad \mathbf{T} = \begin{pmatrix} x^{(1)} & 1 \\ 0 & x^{(1)} \end{pmatrix} = \begin{pmatrix} \alpha & 1 \\ 0 & \alpha \end{pmatrix} \quad \text{and} \quad \mathbf{U} = \begin{pmatrix} -\alpha & 1 \\ -\alpha^2 & 0 \end{pmatrix}$$

574 are an upper-triangular matrix with both diagonal elements equal to $x^{(1)} = \alpha$ and a
 575 matrix whose columns span the invariant subspace of dimension $\mu_1 = 2$, respectively.

In the univariate case, the multiplicity structure is of the form
 $\mathcal{D}[x^{(1)}] = \{\partial_l[x^{(1)}]\}_{l=0}^{\mu_1-1}$. A confluent Vandermonde basis for the $(m = 2)$ -dimensional
 null space of $\mathbf{f}^T = \begin{pmatrix} \alpha^2 & -2\alpha & 1 \end{pmatrix}$ is thus given by

$$\tilde{\mathbf{V}}_1 = (\partial_0[\mathbf{v}_1] \quad \partial_1[\mathbf{v}_1]) = \begin{pmatrix} 1 & 0 \\ \alpha & 1 \\ \alpha^2 & 2\alpha \end{pmatrix}$$

576 with $\mathbf{v}_1(2) = (1 \ \alpha \ \alpha^2)^T$. Take $d^{(1)} = d^{(2)} = 1$, such that the conditions in *Theo-*
 577 *rem 4.2* are satisfied: $d^{(1)} + d^{(2)} = 1 + 1 = 2 \geq 2 = d^* + 1 > d^*$.

578 Next, as mentioned in the proof of *Corollary 4.6*, $\mathbf{Y}(1,1)_{[1,2;3]}$ in (18) may be
 579 constructed from $\mathbf{H}(2) = \tilde{\mathbf{V}}_1 \mathbf{C}^T$ as a special case of $\mathbf{K}(2) = \mathbf{V}(2) \mathbf{C}(2)^T$:
 580

$$\begin{aligned}
 581 \quad \mathbf{Y}_{[1,2;3]}(1,1) &= \left(\frac{(\mathbf{I}_2 \ \mathbf{0}_{2 \times 1}) \cdot \mathbf{H}(2)}{(\mathbf{0}_{2 \times 1} \ \mathbf{I}_2) \cdot \mathbf{H}(2)} \right) = \left(\frac{\mathbf{H}}{\bar{\mathbf{H}}} \right) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 1 \\ -\alpha^2 & 2\alpha \end{pmatrix} = \begin{pmatrix} \mathbf{I}_2 \\ \mathbf{A}_x \end{pmatrix} \\
 582 \quad &= \left(\frac{(\mathbf{I}_2 \ \mathbf{0}_{2 \times 1}) \cdot \tilde{\mathbf{V}}_1(2)}{(\mathbf{0}_{2 \times 1} \ \mathbf{I}_2) \cdot \tilde{\mathbf{V}}_1(2)} \right) \mathbf{C}(2)^T = \left(\frac{\partial_0[\mathbf{v}_1(2)]}{\partial_0[\mathbf{v}_1(2)]} \ \frac{\partial_1[\mathbf{v}_1(2)]}{\partial_1[\mathbf{v}_1(2)]} \right) \mathbf{C}(2)^T = \\
 583 \quad &\qquad\qquad\qquad \begin{pmatrix} 1 & 0 \\ \alpha & 1 \\ \alpha & 1 \\ \alpha^2 & 2\alpha \end{pmatrix} \mathbf{C}(2)^T, \\
 584
 \end{aligned}$$

in which the basis transformation matrix

$$\mathbf{C}(2)^T = \begin{pmatrix} 1 & 0 \\ \alpha & 1 \end{pmatrix}^{-1}.$$

585 It can be verified that $\mathcal{Y}(1,1)$ admits the single-term BTD

$$586 \quad (22) \quad \mathcal{Y}(1,1) = \mathcal{G} \cdot_1 \tilde{\mathbf{V}}_1(1) \cdot_2 \tilde{\mathbf{V}}_1(1) \cdot_3 \mathbf{C}(2) \in \mathbb{C}^{2 \times 2 \times 2}$$

587 in which the core tensor, given by

$$588 \quad (23) \quad \mathbf{G}_{[1;2,3]} = \mathbf{G}_{[2;1,3]} = \left(\begin{array}{cc|cc} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{array} \right),$$

589 can be seen as a three-way variant of a (2×2) Jordan cell. Given that $\partial_0[\mathbf{v}_1] = \mathbf{v}_1$,
 590 (22) becomes

$$591 \quad (24) \quad \mathcal{Y}(1,1) = \mathbf{v}_1(1) \otimes \mathbf{v}_1(1) \otimes \mathbf{c}_{1,1} + \underbrace{\partial_1[\mathbf{v}_1(1)] \otimes \mathbf{v}_1(1) \otimes \mathbf{c}_{1,2} + \mathbf{v}_1(1) \otimes \partial_1[\mathbf{v}_1(1)] \otimes \mathbf{c}_{1,2}}_{\partial_1[\mathbf{v}_1(1) \otimes \mathbf{v}_1(1)] \otimes \mathbf{c}_{1,2}}.$$

592

593 **5. Connection with border rank and typical rank.** The concepts of border
 594 and typical rank belong to the striking differences between linear (matrix) algebra
 595 and multilinear (tensor) algebra. *Subsection 5.1* and *5.2* will discuss border rank and
 596 typical rank of a tensor, respectively, and establish a connection with the BTD in
 597 *Theorem 4.2*. Next to novel fundamental insights, the conclusions at the end of each
 598 subsection will be used to design algorithms in *section 6*.

599 **5.1. Border rank.** The set of tensors that have rank at most R ,

600

$$601 \quad S_R(I_1, I_2, I_3) = \{\mathcal{T} \in \mathbb{C}^{I_1 \times I_2 \times I_3} \mid r_{\mathcal{T}} \leq R\}$$

$$602 \quad = \{\mathcal{T} \in \mathbb{C}^{I_1 \times I_2 \times I_3} \mid \exists \mathbf{A} \in \mathbb{C}^{I_1 \times R}, \mathbf{B} \in \mathbb{C}^{I_2 \times R}, \mathbf{C} \in \mathbb{C}^{I_3 \times R} : \mathcal{T} = \llbracket \mathbf{A}, \mathbf{B}, \mathbf{C} \rrbracket\},$$

604 is not closed for $R \geq 2$ [13]. A consequence is that the computation of the best rank-
 605 R approximation of $\mathcal{T} \in \mathbb{C}^{I_1 \times I_2 \times I_3}$ may result in a sequence of rank- R estimates \mathcal{T}_n

606 that converge to a boundary point $\hat{\mathcal{T}}$ of $S_R(I_1, I_2, I_3)$ which itself has rank $r_{\hat{\mathcal{T}}} > R$.
 607 In such a case, the best rank- R approximation does not exist; the cost function has
 608 an infimum but not a minimum. If a tensor \mathcal{T} can be approximated arbitrarily well
 609 by rank- R tensors, and R is minimal in this sense, then \mathcal{T} is said to have border
 610 rank R . Numerically, it is observed that the convergence towards $\hat{\mathcal{T}}$ is slow and that
 611 some of the rank-1 terms “diverge” in the sense that they become increasingly linearly
 612 dependent, while their norms grow without bound [25, 24]. The columns of \mathbf{A} , \mathbf{B} and
 613 \mathbf{C} that correspond to the diverging rank-1 terms necessarily become more and more
 614 linearly dependent as well.

615 EXAMPLE 5.1. [13, Proposition 4.6] Consider the third-order tensor

$$616 \quad (25) \quad \mathcal{T} = \mathbf{u} \otimes \mathbf{u} \otimes \mathbf{v} + \mathbf{u} \otimes \mathbf{v} \otimes \mathbf{u} + \mathbf{v} \otimes \mathbf{u} \otimes \mathbf{u}$$

617 with \mathbf{u} and \mathbf{v} linearly independent. The tensor \mathcal{T} is known to have rank $r_{\mathcal{T}} = 3 > 2$
 618 and border rank 2 [25]. It is approximated arbitrarily well, for $n \rightarrow \infty$, by a sequence
 619 of two diverging rank-1 terms:

$$621 \quad (26) \quad \mathcal{T}_n = n \left(\mathbf{u} + \frac{1}{n} \mathbf{v} \right) \otimes \left(\mathbf{u} + \frac{1}{n} \mathbf{v} \right) \otimes \left(\mathbf{u} + \frac{1}{n} \mathbf{v} \right) - n \mathbf{u} \otimes \mathbf{u} \otimes \mathbf{u}$$

$$622 \quad = \mathcal{T} + \frac{1}{n} \left(\mathbf{v} \otimes \mathbf{v} \otimes \mathbf{u} + \mathbf{v} \otimes \mathbf{u} \otimes \mathbf{v} + \mathbf{u} \otimes \mathbf{v} \otimes \mathbf{v} + \frac{1}{n} \mathbf{v} \otimes \mathbf{v} \otimes \mathbf{v} \right) = \mathcal{T} + \mathcal{O}\left(\frac{1}{n}\right).$$

623

624
 625 THEOREM 5.2 shows that, if \mathcal{T} is the limit sum of two diverging rank-1 terms, it
 626 has multilinear rank $(2, 2, 2)$ and the core tensor admits a third-order variant of the
 627 Jordan canonical form of (2×2) matrices.

628 THEOREM 5.2. [13, Lemma 4.7] For a group of $R = 2$ diverging rank-1 terms, \mathcal{T}
 629 can be written as

$$630 \quad (27) \quad \mathcal{T} = \mathcal{G} \cdot_1 \mathbf{A} \cdot_2 \mathbf{B} \cdot_3 \mathbf{C}$$

631 where $r_{\mathbf{A}} = r_{\mathbf{B}} = r_{\mathbf{C}} = 2$ and where $\mathcal{G} \in \mathbb{C}^{2 \times 2 \times 2}$ is given by

$$632 \quad (28) \quad \mathbf{G}_{[2;1,3]} = \left(\begin{array}{cc|cc} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{array} \right).$$

633 Moreover, $r_{\mathcal{G}} = r_{\mathcal{T}} = 3$.

634 More generally, divergence can happen in several groups of rank-1 terms, and
 635 groups can involve more than two terms [33]. Divergence can be avoided by decom-
 636 posing the tensor in block terms of proper multilinear rank, rather than rank-1 terms.
 637 The multilinear rank of a block term matches the cardinality of the group of diverging
 638 rank-1 terms that it represents. In [32] third-order variants of the Jordan canonical
 639 form are derived for groups up to four diverging rank-1 terms. In [31, Section 2]
 640 a procedure is proposed to estimate the multilinear rank of the block terms and to
 641 obtain an initialization for the BTD algorithm from a “naively fitted” CPD.

642 Recall from [38] that in the case of simple roots, $\mathcal{Y}(d)$ has rank m . The CPD of
 643 $\mathcal{Y}(d)$ can be related to a matrix EVD in which all eigenvalues are distinct. Example 5.3
 644 illustrates that $\mathcal{Y}(d^{(1)}, d^{(2)})$ in Theorem 4.2 has border rank m in the case of multiple
 645 roots. Indeed, roots with multiplicity greater than 1 may be seen as the limit case
 646 of simple roots that get closer and closer. In Theorem 4.2 the m_0 groups of μ_k

647 diverging rank-1 terms are collected in m_0 block terms of multilinear rank (μ_k, μ_k, μ_k) ,
 648 $k = 1 : m_0$. While the CPD is related to an EVD in the case of only distinct roots,
 649 the BTD in (19) may be seen as a third-order generalization of the Jordan canonical
 650 form when there are eigenvalues that have an algebraic multiplicity greater than the
 651 geometric multiplicity.

652 **EXAMPLE 5.3.** Consider again the polynomial equation in *Example 4.7*. Recall
 653 that we built $\mathcal{Y}(1,1)$ from the slices \mathbf{I}_2 and \mathbf{A}_x . The matrix $(\mathbf{I}_2)^{-1} \mathbf{A}_x = \mathbf{A}_x$ has a
 654 double eigenvalue α with geometric multiplicity 1. The matrix \mathbf{A}_x cannot be diago-
 655 nalized but it does admit a Jordan canonical form. Further, $\mathcal{Y}(1,1)$ itself admits the
 656 third-order variant of the Jordan canonical form in *Theorem 5.2*, i.e. (22) is an in-
 657 stance of (27) and (23) matches (28). One can show that $r_{\mathcal{Y}} = 3$ but that $\mathcal{Y}(1,1)$ has
 658 border rank $m = 2$. Trying to compute a rank-2 PD of $\mathcal{Y}(1,1)$ results in a sequence
 659 of $m = 2$ diverging rank-1 terms as in *Example 5.1*.

660 On the other hand, *Example 4.3* exhibited in fact the third-order variant of a
 661 (4×4) Jordan cell in the form of the core tensor $\mathcal{G}(2,2)$. The root with multiplicity
 662 4 led to a block term of border rank 4. Fitting a rank-4 PD results in a sequence of
 663 $m = 4$ diverging rank-1 terms.

664 We can conclude that, if we proceed in the multiple root case as we have done
 665 for simple roots in [38], i.e. by fitting a rank- m CPD to $\mathcal{Y}(1, d-1)$, this will result
 666 in m_0 groups of diverging rank-1 terms, with μ_k rank-1 terms in the k th group. Such
 667 divergence does not occur if we fit the BTD (19) to $\mathcal{Y}(d^{(1)}, d^{(2)})$. The crucial point is
 668 not to split a multilinear rank- (μ_k, μ_k, μ_k) term into terms of lower multilinear rank,
 669 such as rank-1 terms. As in [31, Section 2], estimates of the multiplicities μ_k and an
 670 initialization for the BTD algorithm may nevertheless be obtained from a “naive” use
 671 of the algorithm for simple roots in [38] (see section 6 for an illustration).

672 **5.2. Rank over the real or the complex field.** The rank of a tensor depends
 673 on the field of the entries. Consider for instance $\mathcal{T} \in \mathbb{R}^{2 \times 2 \times 2}$ whose entries are sampled
 674 randomly from a continuous probability distribution. If \mathbf{A} , \mathbf{B} and \mathbf{C} are constrained
 675 to be real, then $r_{\mathcal{T}} = 2$ and $r_{\mathcal{T}} = 3$ occur both with nonzero probability — whereas if
 676 \mathbf{A} , \mathbf{B} and \mathbf{C} can be complex, $r_{\mathcal{T}} = 2$ occurs with probability 1 [23, 2]. When the rank
 677 takes more than one value with nonzero possibility, the values that occur are called
 678 typical. A rank value that occurs with probability 1, is called generic.

679 The roots of a system of polynomial equations with real-valued coefficients are
 680 real-valued or appear in complex conjugated pairs. *Example 5.4* shows that a simple
 681 pair of complex conjugated roots yields a real-valued block term of multilinear rank
 682 $(2, 2, 2)$ that takes rank 2 over \mathbb{C} but rank 3 over \mathbb{R} . In general, the computation
 683 of the roots of a system of polynomial equations with real-valued coefficients can be
 684 done in \mathbb{R} provided we allow block terms, where block terms that take rank 2 over
 685 \mathbb{C} but rank 3 over \mathbb{R} , capture simple pairs of complex conjugated roots. Block terms
 686 that capture a pair of real-valued simple roots have rank 2 over *both* \mathbb{C} and \mathbb{R} ; such
 687 terms can be further decomposed in two real-valued rank-1 terms that correspond to
 688 the individual roots.

689 **EXAMPLE 5.4.** Consider the univariate polynomial equation

$$690 \quad f(x) = x^2 - 2x + 2 = 0$$

691 of degree $d = m = 2$. There are $m = 2$ complex conjugated roots: $x^{(1)} = 1 + i$ and
 692 $x^{(2)} = 1 - i$. The degree of regularity $d^* = 1$. At $d = d^* + 1 = 2$, $\mathcal{Y}(1, d-1) =$

693 $\mathcal{Y}(1, 1) \in \mathbb{R}^{2 \times 2 \times 2}$ is constructed from $\mathbf{K}(2) (= \mathbf{V}(2)\mathbf{C}(2)^T) \in \mathbb{R}^{3 \times 2}$ as follows:

$$694 \quad \mathbf{Y}_{[1,2;3]}(1, 1) = \left(\frac{\begin{pmatrix} \mathbf{I}_2 & \mathbf{0}_{2 \times 1} \\ \mathbf{0}_{2 \times 1} & \mathbf{I}_2 \end{pmatrix} \cdot \mathbf{K}(2)}{\begin{pmatrix} \mathbf{0}_{2 \times 1} & \mathbf{I}_2 \end{pmatrix} \cdot \mathbf{K}(2)} \right) = \begin{pmatrix} 1 & 1 \\ \frac{1+i}{1+i} & \frac{1-i}{1-i} \\ \frac{1+i}{(1+i)^2} & \frac{1-i}{(1-i)^2} \end{pmatrix} \mathbf{C}(2)^T \in \mathbb{R}^{(2 \cdot 2) \times 2}.$$

695 Since both roots are simple, \mathcal{Y} admits the CPD $\mathcal{Y}(1, 1) = \llbracket \mathbf{V}(1), \mathbf{V}(1), \mathbf{C}(2) \rrbracket$ with

$$696 \quad \mathbf{V}(1) = \begin{pmatrix} 1 & 1 \\ 1+i & 1-i \end{pmatrix}.$$

697 We can rewrite the CPD as a single-term BTD:

$$698 \quad \mathcal{Y}(1, 1) = \mathcal{G}(1, 1) \cdot_1 \mathbf{A}(1) \cdot_2 \mathbf{B}(1) \cdot_3 \mathbf{C}(2)$$

699 in which

$$700 \quad \mathbf{G}_{[1;3,2]}(1, 1) = \left(\begin{array}{cc|cc} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{array} \right)$$

701 and in which the (2×2) factor matrices $\mathbf{A}(1) = \mathbf{B}(1) = \mathbf{V}(1)$ and $\mathbf{C}(2)$ are complex-
702 valued. From the sparsity pattern of \mathcal{G} it is obvious that $r_{\mathcal{G}} = r_{\mathcal{Y}} = m = 2$.

703 The tensor $\mathcal{Y}(1, 1)$ can equally well be decomposed as

$$704 \quad \mathcal{Y}(1, 1) = \tilde{\mathcal{G}}(1, 1) \cdot_1 \tilde{\mathbf{A}}(1) \cdot_2 \tilde{\mathbf{B}}(1) \cdot_3 \tilde{\mathbf{C}}(2),$$

705 in which

$$706 \quad \tilde{\mathcal{G}}(1, 1) = \mathcal{G}(1, 1) \cdot_1 \left(\mathbf{M}^{(1)} \right)^{-1} \cdot_2 \left(\mathbf{M}^{(2)} \right)^{-1} \cdot_3 \left(\mathbf{M}^{(3)} \right)^{-1},$$

707 and $\tilde{\mathbf{A}}(1) = \mathbf{A}(1)\mathbf{M}^{(1)}$, $\tilde{\mathbf{B}}(1) = \mathbf{B}(1)\mathbf{M}^{(2)}$, $\tilde{\mathbf{C}}(1) = \mathbf{C}(1)\mathbf{M}^{(3)} \in \mathbb{C}^{2 \times 2}$,

708 where $\mathbf{M}^{(1)}, \mathbf{M}^{(2)}, \mathbf{M}^{(3)} \in \mathbb{C}^{2 \times 2}$ are invertible basis transformation matrices. If we
709 take

$$710 \quad \mathbf{M}^{(1)} = \mathbf{M}^{(2)} = \mathbf{M}^{(3)} = \mathbf{M} = \begin{pmatrix} \frac{1}{2} & \frac{1}{2i} \\ \frac{1}{2} & -\frac{1}{2i} \end{pmatrix},$$

711 then $\tilde{\mathbf{A}}(1), \tilde{\mathbf{B}}(1), \tilde{\mathbf{C}}(1)$ are real-valued and

$$712 \quad \tilde{\mathbf{G}}_{[1;3,2]}(1, 1) = \left(\begin{array}{cc|cc} 2 & 0 & 0 & -2 \\ 0 & -2 & -2 & 0 \end{array} \right).$$

713 The core tensor $\tilde{\mathcal{G}}(1, 1) \in \mathbb{R}^{2 \times 2 \times 2}$ has rank 3 over \mathbb{R} . (On the other hand, like $\mathcal{Y}(1, 1)$,
714 it has rank 2 over \mathbb{C} .)

715 **6. Algorithm.** The goal of this section is to use the fundamental insights from
716 the previous sections to design numerical methods for the multivariate rootfinding
717 problem.

718 **6.1. A BTD based root-finding method.** [Theorem 4.4](#) hints at an algebraic
719 BTD-based algorithm illustrated in [Algorithm 1](#) for finding the roots of a polynomial
720 system that can handle roots multiple roots. It generalizes the algebraic method in [\[38,](#)
721 [Algorithm 1\]](#). For roots with multiplicities, the algorithm first finds the column spaces
722 of the BTD factor matrices $\mathbf{B} \stackrel{\text{def}}{=} (\mathbf{B}_1 \ \dots \ \mathbf{B}_{m_0}) \in \mathbb{C}^{q(d^{(2)}) \times m}$. These correspond
723 to the μ_k -dimensional multivariate confluent Vandermonde subspaces associated with
724 the dual spaces of the m_0 disjoint roots.

Algorithm 1 BTD for multivariate polynomial root finding

Input: A system $f_i \in \mathbb{C}_{d_i}^n, i = 1 : n$, in $n + 1$ projective unknowns $x_j \in \mathbb{C}, j = 0 : n$.

Output: Roots $x_1^{(k)}, \dots, x_n^{(k)}$ and multiplicities $\mu_k, k = 1 : m_0$.

- 1: Choose $d^{(1)}, d^{(2)}$ such that $d = d^{(1)} + d^{(2)} \geq d^* + 1$ and $d^{(1)}, d^{(2)}$ satisfy the conditions of [Theorem 4.4](#).
- 2: Construct Macaulay matrix $\mathbf{M}(d)$.
- 3: Compute null space basis $\mathbf{K}(d) \leftarrow \text{null}(\mathbf{M}(d))$.
- 4: **for** $j = 0 : q(d^{(1)}) - 1$ **do**
- 5: $\mathcal{Y}(j + 1, :, :) \leftarrow \bar{\mathbf{S}}^{(j)}(d^{(2)}) \cdot \mathbf{K}(d)$.
- 6: Compute the SVD $\mathbf{Y}_{[2;1,3]} = \mathbf{U}^{(2)} \cdot \mathbf{\Sigma}^{(2)} \cdot \mathbf{U}^{(1,3)H}$.
- 7: Orthogonal compression: $\mathcal{Y}_c \leftarrow \mathcal{Y} \cdot \mathbf{U}^{(2)H}$.
- 8: Compute the BTD

$$(29) \quad \mathcal{Y}_c = \sum_{k=1}^{m_0} \mathcal{G}_k \cdot_1 \mathbf{A}_k \cdot_2 \tilde{\mathbf{B}}_k \cdot_3 \mathbf{C}_k$$

with $\mathcal{G}_k \in \mathbb{C}^{\mu_k \times \mu_k \times \mu_k}$, $\mathbf{A}_k \in \mathbb{C}^{q(d^{(1)}) \times \mu_k}$, and $\tilde{\mathbf{B}}_k, \mathbf{C}_k \in \mathbb{C}^{m \times \mu_k}, k = 1 : m_0$.

- 9: Expand $\mathbf{B}_k = \mathbf{U}^{(2)} \tilde{\mathbf{B}}_k \in \mathbb{C}^{q(d^{(2)}) \times \mu_k}$ and retrieve the roots via generalized ESPRIT approach, $k = 1 : m_0$.
- 10: **return** $x_1^{(k)}, \dots, x_n^{(k)}$ and $\mu_k, k = 1 : m_0$.

725 We comment on the main steps of [Algorithm 1](#):

726 **Step 1.** The degrees $d^{(1)}, d^{(2)}$ have to be chosen sufficiently large according to the
 727 conditions of [Theorem 4.4](#) to ensure uniqueness of the BTD and to allow its algebraic
 728 computation. The condition $d^{(1)} \geq \max\{1, \max_k \delta_k\}$ leads to the obstacle that the
 729 depths δ_k of the roots are generally unknown beforehand. It holds $\delta_k \leq \mu_k - 1$, but
 730 also the multiplicities μ_k are generally not known either. However, if the degree $d^{(1)}$ is
 731 chosen large enough, the number m_0 of distinct roots and the individual multiplicities
 732 μ_k are directly obtained in the course of the algebraic computation of the BTD in
 733 [Step 8](#), where m_0 is the number of detected terms and the μ_k appear as the sizes
 734 of the individual blocks in the factor matrices. One obvious possibility is to use the
 735 upper bound $\delta_k \leq \max_i d_i$ and set $d^{(1)} = \max_i d_i$. However, such an increase in d
 736 would lead to a larger Macaulay matrix and make the computation of basis for the
 737 null space more expensive.

738 **Steps 2 – 5.** These are the same calculations as in [[38](#), [Algorithm 1](#)] for simple
 739 roots. The only difference is that in [Step 5](#), more than $n + 1$ selections $\bar{\mathbf{S}}^{(j)}(d^{(2)})$ are
 740 applied if $d^{(1)} > 1$. These execute a generalized spatial smoothing with monomials of
 741 degree greater than one.

742 **Steps 6, 7.** As in the root-finding procedure for simple roots [[38](#), [Algorithm 1](#)]
 743 compression of \mathcal{Y} is carried out. This reduces the computational load in the later
 744 steps.

745 **Step 8.** Here the factor matrices and cores of the BTD (29) are obtained using the
 746 algebraic computation outlined in [subsection 3.1.2](#). The main computational step is
 747 the block-diagonalization by similarity of an $m \times m$ matrix. This block-diagonalization
 748 returns $\tilde{\mathbf{B}}_k, \mathbf{C}_k \in \mathbb{C}^{m \times \mu_k}, k = 1 : m_0$, where the column dimensions match the
 749 multiplicity μ_k of the k th root (provided $d^{(1)}, d^{(2)}$ have been chosen appropriately).

750 The blocks $\mathbf{B}_k = \mathbf{U}^{(2)}\tilde{\mathbf{B}}_k$, \mathbf{C}_k are the blocks of the second and third factor matrix \mathbf{B} ,
 751 \mathbf{C} of the BTD (19). With $\mathbf{B}_k, \mathbf{C}_k$ the blocks \mathbf{A}_k of the first factor matrix and cores
 752 \mathcal{G}_k can be obtained. In the next step 9 we will see that for obtaining the roots, only
 753 \mathbf{A}_k or \mathbf{B}_k are required.

754 As an alternative one could, similar to the CPD root finding method in [38], compute
 755 the BTD (19) in step 8 by, e.g., NLS type methods [29]. Although this requires
 756 in theory less stringent conditions on $d^{(1)}, d^{(2)}$, in practice the performance of such
 757 NLS methods is highly dependent on good initial guesses. Thus, the outcome of the
 758 algebraic method can be used as initial guess for NLS methods which would then
 759 refine the quality of the result.

760 **Step 9.** The decomposition of \mathcal{Y} obtained in step 8 yields a splitting of contribu-
 761 tions of the m_0 different roots. Rank-1 terms are given by vectors $\mathbf{a}_k = \mathbf{A}_k \in \mathbb{C}^{q(d^{(1)})}$,
 762 $\mathbf{b}_k = \mathbf{B}_k \in \mathbb{C}^{q(d^{(2)})}$ and belong to simple roots ($\mu_k = 1$) which can be readily retrieved
 763 from \mathbf{A}_k or \mathbf{B}_k by means of a simply scaling (e.g., dividing \mathbf{A}_k by its first entry) as
 764 discussed in [38]. Alternatively, the multiplicative shift structure of multivariate Van-
 765 dermonde vectors and matrices can be used: $\tilde{\mathbf{S}}^{(i)} \mathbf{A}_k = \tilde{\mathbf{S}}^{(0)} \mathbf{A}_k \cdot x_i^{(k)}$, $i = 1 : n$, where
 766 $\tilde{\mathbf{S}}^{(0)}, \tilde{\mathbf{S}}^{(i)}$ select the rows associated to monomials of degree 0 to $d^{(1)} - 1$ and, respec-
 767 tively, the rows associated to monomials up to degree $d^{(1)}$ where x_i is of degree at
 768 least one. Using the \mathbf{b}_k vectors works in the same way.

769 Retrieving the roots with multiplicities requires some additional work because,
 770 due to the (multi)linear transformation indeterminacies, the computed block matrices
 771 \mathbf{A}_k and \mathbf{B}_k do not directly reveal the roots. The roots can be found from \mathbf{A}_k or
 772 \mathbf{B}_k by using the generalized multiplicative shift structure of confluent multivariate
 773 Vandermonde matrices, see Lemma B.4. We will illustrate this using the \mathbf{A}_k blocks
 774 here, but the variant using the \mathbf{B}_k works in the same way. Note that we originally
 775 used this multiplicative shift structure to derive the BTD (19) in Theorem 4.2. Recall
 776 that $\mathbf{A}_k = \tilde{\mathbf{V}}_k(d^{(1)})\tilde{\mathbf{M}}_k$ for some invertible $\tilde{\mathbf{M}}_k \in \mathbb{C}^{\mu_k \times \mu_k}$, $k = 1 : m_0$. For an affine
 777 root \mathbf{x}_k with multiplicity $\mu_k > 1$ and depth $\delta_k \leq \mu_k - 1$, we have for the corresponding
 778 confluent multivariate Vandermonde matrix $\tilde{\mathbf{V}}_k(d^{(2)})$

$$779 \quad \tilde{\mathbf{S}}^{(i)} \tilde{\mathbf{V}}_k(d^{(1)}) = \tilde{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_k(d^{(1)}) \mathbf{J}_k^{(i)}, \quad i = 1 : n,$$

780 where $\tilde{\mathbf{S}}^{(0)}$ selects the first $I_k \geq \mu_k$ rows of $\tilde{\mathbf{V}}_k(d^{(1)})$ such that $\tilde{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_k(d^{(1)}) \in \mathbb{C}^{I_k \times \mu_k}$
 781 has full column rank, $\tilde{\mathbf{S}}^{(i)}$ selects the rows of $\tilde{\mathbf{V}}_k(d^{(1)})$ onto which these $I_k \geq \mu_k$
 782 monomials are mapped after a multiplication with the i th variable x_i , and $\mathbf{J}_k^{(i)} \in$
 783 $\mathbb{C}^{\mu_k \times \mu_k}$ is upper triangular with $x_i^{(k)}$ (the value of the i th variable of the k th distinct
 784 root) on the diagonal, see Lemma B.4 in Appendix B.1 or [15, Section 4.4], [14,
 785 Section 6.1] for details. Using $\tilde{\mathbf{V}}_k(d^{(1)}) = \mathbf{A}_k \tilde{\mathbf{M}}_k^{-1}$ yields

$$786 \quad \left(\tilde{\mathbf{S}}^{(0)} \mathbf{A}_k\right)^\dagger \tilde{\mathbf{S}}^{(i)} \mathbf{A}_k = \tilde{\mathbf{M}}_k^{-1} \mathbf{J}_k^{(i)} \tilde{\mathbf{M}}_k \stackrel{\text{def}}{=} \tilde{\mathbf{J}}_k^{(i)}, \quad i = 1 : n.$$

787 In other words, $\tilde{\mathbf{J}}_k^{(i)}$ can be obtained by solving the linear system $\left(\tilde{\mathbf{S}}^{(0)} \mathbf{A}_k\right) \tilde{\mathbf{J}}_k^{(i)} =$
 788 $\tilde{\mathbf{S}}^{(i)} \mathbf{A}_k$ and it has a single distinct eigenvalue $x_i^{(k)}$ with algebraic multiplicity μ_k . This
 789 eigenvalue can be retrieved by $x_i^{(k)} = \text{trace}(\tilde{\mathbf{J}}_k^{(i)})/\mu_k$ or from a Schur decomposition
 790 $\tilde{\mathbf{J}}_k^{(i)} = \mathbf{Q}_{k,i}^H \mathbf{R}_{k,i} \mathbf{Q}_{k,i}$ with $\mathbf{Q}_{k,i}$ unitary and $\mathbf{R}_{k,i}$ upper-triangular with $x_i^{(k)}$ on the
 791 diagonal.

792 Step 9 is the only part of Algorithm 1 that needs to be slightly adapted in case of
 793 roots at infinity. If $x_0^{(k)} = 0, x_1^{(k)}, \dots, x_n^{(k)}$ is a root in the $n+1$ projective coordinates,

794 $\tilde{\mathbf{S}}^{(0)}\mathbf{A}_k$ will not have full column rank because $\tilde{\mathbf{V}}_k(d^{(1)})$ will have zero columns and
 795 zero top rows. Thus, we use a rank test on $\tilde{\mathbf{S}}^{(0)}\mathbf{A}_k$ to decide whether the k th root is
 796 projective or not. If $r_{\tilde{\mathbf{S}}^{(0)}\mathbf{A}_k} < \mu_k$ then the k th root is at infinity and we set $x_0^{(k)} = 0$.
 797 Otherwise, we are in the affine situation and set $x_0^{(k)} = 1$ and proceed as outlined
 798 above. For a root at infinity, recall that the components $x_i^{(k)}$, $i = 1 : n$ are only
 799 determined up to scalar factor $\lambda \neq 0$. We continue in this case by testing if $\tilde{\mathbf{S}}^{(i)}\mathbf{A}_k$
 800 has full column rank for $i = 1 : n$. If $r_{\tilde{\mathbf{S}}^{(i)}\mathbf{A}_k} < \mu_k$ we set $x_i^{(k)} = 0$, otherwise we
 801 continue as in the affine case to retrieve the component $x_i^{(k)}$. Note that at least one
 802 component $x_i^{(k)}$, $i = 1 : n$ has to be nonzero.

803 In the form presented in [Algorithm 1](#), the method will return the roots and the
 804 individual multiplicities, but not their complete multiplicity structures. One possibil-
 805 ity to get the multiplicity structure for a known root with known multiplicity $\mu_k > 1$
 806 is to find the differential functionals $c_{kl} = \sum_j \beta_j \partial_j$, $l = 0 : \mu_k - 1$ from all possible dif-
 807 ferential functional monomials ([Definition 3.3](#)) up to order $\mu_k - 1$: $\partial_{\mathbf{0}}, \partial_{1,0,\dots,0}, \dots, \partial_{\mathbf{h}}$,
 808 $|\mathbf{h}| = \mu_k - 1$. It holds

$$809 \quad \tilde{\mathbf{V}}_k(d) = (c_{k0}[\mathbf{v}_k] \quad \dots \quad c_{k\mu_k-1}[\mathbf{v}_k]) = \underbrace{(\partial_{\mathbf{0}}[\mathbf{v}_k] \quad \partial_{1,0,\dots,0}[\mathbf{v}_k] \quad \dots \quad \partial_{\mathbf{h}}[\mathbf{v}_k])}_{\stackrel{\text{def}}{=} \mathbf{U}_k} \mathbf{P}_k,$$

810 where $\mathbf{P}_k \in \mathbb{C}^{q(\mu_k-1) \times \mu_k}$ holds the coefficients β of the functional c_{kl} . Only $\mathbf{U}_k \in$
 811 $\mathbb{C}^{q(d) \times q(\mu_k-1)}$ is explicitly known in the above equality. Since $\mathbf{M}(d)\tilde{\mathbf{V}}_k(d) = \mathbf{0}$, the
 812 matrix \mathbf{P}_k can be computed from the nullspace problem

$$813 \quad (\mathbf{M}(d)\mathbf{U}_k) \mathbf{P}_k = \mathbf{0},$$

814 see also [[1](#), Section 3.6.2] for similar approaches. Alternatively, one could resort to
 815 algorithms for computing the multiplicity structure [[26](#), [28](#), [7](#), [41](#), [6](#)].

816 **6.2. A recursive root-finding method.** The BTD in [Algorithm 1](#) and [sec-](#)
 817 [tion 5](#) prompt the unconstrained *recursive* polynomial root-finding [Algorithm 2](#). The
 818 algorithm allows us to (recursively) detect various (nested) structures in the null space
 819 of the Macaulay matrix. We give this algorithm as an illustration of the remarkable
 820 new possibilities in our framework.

821 Some explanation is in order. In [Example 5.4](#) we combined (a) pair(s) of rank-1
 822 terms, which per definition are pairs of multilinear rank-(1, 1, 1) terms, to rewrite
 823 the CPD of $\mathcal{Y}(1, d-1)$ as a BTD. That is, we expressed $\mathcal{Y}(1, d-1)$ as a BTD with
 824 (one) multilinear rank-(2, 2, 2) term(s). There is no reason why we should refrain to
 825 further combine pairs of multilinear rank-(2, 2, 2) terms to obtain a BTD in multilinear
 826 rank-(4, 4, 4) term(s), and so on. The converse of this bottom-up reasoning is the
 827 top-down schematic in [Figure 3](#); [Algorithm 2](#) is the implied recursive root-finding
 828 algorithm. It proceeds as follows. Take the initial input $\hat{\mathcal{Y}} = \hat{\mathcal{Y}}(1, d-1)$ embodying
 829 all $R = m$ roots. Next, compute the BTD in [step 7](#) with, for instance, $R_1 = \lfloor m/2 \rfloor$ and
 830 $R_2 = \lceil m/2 \rceil$. Then descend to the next level of the tree in [Figure 3](#). Recursively run
 831 the same procedure on $\hat{\mathcal{Y}}_1$ embodying $R = R_1 = \lfloor m/2 \rfloor$ roots and on $\hat{\mathcal{Y}}_2$ embodying
 832 $R = R_2 = \lceil m/2 \rceil$ roots. After having repeated this procedure $\mathcal{O}(\log_2 m)$ times, each
 833 CPD in [step 2](#) in [Algorithm 2](#) (at the leaf nodes in [Figure 3](#)) reveals the minimum
 834 possible $R = 2$ roots left. The columns of the obtained factor matrices $\hat{\mathbf{A}}_n$, $\hat{\mathbf{B}}_n$ and
 835 $\hat{\mathbf{C}}_n$ could thereby serve as an initialization for computing the BTD or the CPD at a
 836 lower level.

Fig. 3: Tree-like schematic of a complete run of [Algorithm 2](#) for $\hat{\mathcal{Y}} = \hat{\mathcal{Y}}(1, d-1) \in \mathbb{C}^{(n+1) \times m \times m}$. BTDs at the top levels (second and third mode dimensions $R > 2$) are indicated in black and CPDs in the leaves (with $R \leq 2$) are indicated in white. The rank values $r_{\hat{\mathcal{Y}}} = R$ are also depicted in each node.

Algorithm 2 Recursive multivariate polynomial root-finding

Input: A compressed $\hat{\mathcal{Y}} \in \mathbb{C}^{(n+1) \times R \times R}$ ($R \leq m$) for the system $f_i \in \mathbb{C}_{d_i}^n, i = 1 : n$, in the $n+1$ projective unknowns $x_j \in \mathbb{C}, j = 0 : n$, with $m_0 = m$ simple roots.

Output: $\{\mathbf{x}^{(k)}\}_{k=1}^R$

- 1: **if** $R \leq 2$ **then** ▷ termination
- 2: Compute the R -term CPD $\hat{\mathcal{Y}} = \llbracket \hat{\mathbf{A}}, \hat{\mathbf{B}}, \hat{\mathbf{C}} \rrbracket$.
- 3: $\mathbf{X} \leftarrow \sim \hat{\mathbf{A}}$.
- 4: **return** \mathbf{X}
- 5: **else** ▷ divide
- 6: $R_1 \leftarrow \lfloor R/2 \rfloor$ and $R_2 \leftarrow \lceil R/2 \rceil$.
- 7: Compute the BTD

$$\hat{\mathcal{Y}} = \underbrace{\hat{\mathcal{G}}_1 \cdot_1 \hat{\mathbf{A}}_1 \cdot_2 \hat{\mathbf{B}}_1 \cdot_3 \hat{\mathbf{C}}_1}_{=\hat{\mathcal{Y}}_1 \in \mathbb{C}^{n+1 \times R_1 \times R_1}} + \underbrace{\hat{\mathcal{G}}_2 \cdot_1 \hat{\mathbf{A}}_2 \cdot_2 \hat{\mathbf{B}}_2 \cdot_3 \hat{\mathbf{C}}_2}_{=\hat{\mathcal{Y}}_2 \in \mathbb{C}^{n+1 \times R_2 \times R_2}}$$

in which $\hat{\mathcal{G}}_1 \in \mathbb{C}^{R_1 \times R_1 \times R_1}$ and $\hat{\mathcal{G}}_2 \in \mathbb{C}^{R_2 \times R_2 \times R_2}$.

- 8: Compress $\hat{\mathcal{Y}}_1$ and $\hat{\mathcal{Y}}_2$ using the MLSVD.
 - 9: **return** $\{ \text{ALGORITHM 2}(\hat{\mathcal{Y}}_1), \text{ALGORITHM 2}(\hat{\mathcal{Y}}_2) \}$ ▷ conquer
-

837 The root node in [Figure 3](#) embodies (a full basis for) the $(R = m)$ -dimensional
 838 null space of the Macaulay matrix. The lower-level nodes embody increasingly lower-
 839 dimensional nested subspaces $\subseteq \mathbb{C}^n$. They provide an increasingly finer-grained view
 840 on the roots $\mathbf{x}^{(k)} \in \mathbb{C}^n$ of the system. One could alternatively terminate the recursion
 841 over \mathbb{R} at a multilinear rank- $(2, 2, 2)$, rank-3 term that corresponds to a pair of complex
 842 conjugated roots, or at a multilinear rank- (μ_k, μ_k, μ_k) term. In the latter case the leaf
 843 node would embody the μ_k -dimensional dual space $\mathcal{D}[\mathbf{x}^{(k)}]$. Owing to many NLS
 844 runs, the recursive procedure does in the case of simple roots not compete with [\[38,](#)
 845 [Algorithm 1\]](#) in terms of computational cost, but it is extremely flexible and interesting
 846 conceptually. One could for instance decide to “zoom in” on a select cluster of roots
 847 in one block term. [Example 6.1](#) sketches the idea.

848 EXAMPLE 6.1. Consider first the univariate case. Say that we are only interested

849 in the roots of a univariate polynomial $f(x)$ within a Δ -neighborhood of a given x ,
850 i.e. roots $x + \delta$, $|\delta| \leq \Delta$. For

$$851 \quad \mathbf{v}_x = (1 \quad x \quad x^2 \quad \dots \quad x^d)^T \quad \text{and} \quad \mathbf{v}_{x+\delta} = (1 \quad x + \delta \quad (x + \delta)^2 \quad \dots \quad (x + \delta)^d)^T$$

852 we have

$$853 \quad (30) \quad \cos(\mathbf{v}_x \triangleleft \mathbf{v}_{x+\delta}) = \frac{\langle \mathbf{v}_x, \mathbf{v}_{x+\delta} \rangle}{\|\mathbf{v}_x\| \|\mathbf{v}_{x+\delta}\|} = \frac{\frac{1 - [x(x+\delta)]^{d+1}}{1 - x(x+\delta)}}{\sqrt{\frac{1 - [x^2]^{d+1}}{1 - x^2}} \sqrt{\frac{1 - [(x+\delta)^2]^{d+1}}{1 - (x+\delta)^2}}}.$$

854 Evidently, $\lim_{|\delta| \leq \Delta \rightarrow 0} \cos(\mathbf{v}_x \triangleleft \mathbf{v}_{x+\delta}) = 1$. To assess whether a candidate root y is
855 sufficiently close to x to be of further interest, we will consider $|x - y|$, if both values
856 are available. If the Vandermonde vectors \mathbf{v}_x and \mathbf{v}_y are available, we may obviously
857 also compare the latter, as is clear from (30). However, the block terms in step 7
858 of Algorithm 2 are characterized by confluent Vandermonde subspaces rather than
859 individual Vandermonde vectors. The subspaces may be generated by several roots,
860 which can themselves be simple or have multiplicity greater than 1. Here, we can
861 assess the angle between a subspace (say \mathcal{S}) and Vandermonde vector \mathbf{v}_x of matching
862 size. For a block term that captures (possibly among other roots) a root y that is close
863 to x , $\cos(\mathbf{v}_x \triangleleft \mathcal{S})$ is bounded from below by (30) for a given tolerance Δ . Conversely,
864 we can discard the block terms for which $\cos(\mathbf{v}_x \triangleleft \mathcal{S})$ is not large enough, since their
865 subspaces cannot contain a Vandermonde vector with a generator sufficiently close to
866 x .

867 In the multivariate case it is possible to assess the proximity for all variables
868 together. Let us consider the bivariate case by way of example. Let $\mathbf{\Delta} = (\delta_1 \quad \delta_2)^T$
869 demarcate a region around $\mathbf{x} = (x_1 \quad x_2)^T$. For assessing the proximity of $\mathbf{v}_{\mathbf{x}} =$
870 $\mathbf{v}_{x_1} \otimes \mathbf{v}_{x_2}$ and $\mathbf{v}_{\mathbf{x}+\delta} = \mathbf{v}_{x_1+\delta_1} \otimes \mathbf{v}_{x_2+\delta_2}$, note that

$$\begin{aligned} 871 \quad \langle \mathbf{v}_{x_1} \otimes \mathbf{v}_{x_2}, \mathbf{v}_{x_1+\delta_1} \otimes \mathbf{v}_{x_2+\delta_2} \rangle &= (\mathbf{v}_{x_1} \otimes \mathbf{v}_{x_2})^H (\mathbf{v}_{x_1+\delta_1} \otimes \mathbf{v}_{x_2+\delta_2}) \\ 872 &= (\mathbf{v}_{x_1}^H \mathbf{v}_{x_1+\delta_1}) \cdot (\mathbf{v}_{x_2}^H \mathbf{v}_{x_2+\delta_2}) \\ 873 &= \langle \mathbf{v}_{x_1}, \mathbf{v}_{x_1+\delta_1} \rangle \cdot \langle \mathbf{v}_{x_2}, \mathbf{v}_{x_2+\delta_2} \rangle, \end{aligned}$$

875 and that $\|\mathbf{v}_{x_1} \otimes \mathbf{v}_{x_2}\| = \|\mathbf{v}_{x_1}\| \cdot \|\mathbf{v}_{x_2}\|$. This allows the threshold (30) to be replaced
876 by a product of such thresholds.

877 **7. Experimental results.** This section contains the results of some numerical
878 experiments that illustrate the potential of our approach.

879 **7.1. BTD-based root-finding.** As an illustration of the discussion in subsection
880 5.1 we compare fitting of the m_0 -term BTD (19) and the m -term CPD (2) in the
881 multiple root case, and we showcase the divergence of rank-1 terms when fitting the
882 CPD. By way of example, we consider the system [35, Example 1.3.1]

$$883 \quad (31) \quad \begin{cases} f_1(x_1, x_2) = x_1 x_2 - 2x_2 = 0 \\ f_2(x_1, x_2) = 2x_2^2 - x_1^2 = 0 \end{cases}$$

884 shown in Figure 4a. We have $s = n = 2$, $d_0 = 2$, $d^* = 2 + 2 - 2 = 2$, and $m = 2 \cdot 2 = 4$,
885 but $m_0 = 3$. The system has $m_0 = 3 < 4 = m$ disjoint (and affine) roots

$$886 \quad \mathbf{x}^{(1)} = \begin{pmatrix} x_1^{(1)} & x_2^{(1)} \end{pmatrix}^T = (0 \quad 0)^T \quad \text{and} \quad \begin{pmatrix} x_1^{(2,3)} & x_2^{(2,3)} \end{pmatrix}^T = (2 \quad \pm\sqrt{2})^T$$

Fig. 4: (a) Zero level curves of f_1 (---) and f_2 (—) in (31). The roots are marked with ‘o’. (b) Convergence of an optimization-based NLS type algorithm to fit a CPD (---) and a BTD (—) to $\mathcal{Y}(1,1)$ in (32) as a function of the iteration step.

887 with multiplicity $\mu_1 = 2$ and $\mu_2 = \mu_3 = 1$, respectively. The confluent multivariate
 888 Vandermonde basis $\tilde{\mathbf{V}}(2)$ for $\text{null}(\mathbf{M}(d^*)) = \text{null}(\mathbf{M}(2))$ is given by

$$889 \quad \tilde{\mathbf{V}}(2) = (\tilde{\mathbf{V}}_1(2) \mid \tilde{\mathbf{v}}_2(2) \mid \tilde{\mathbf{v}}_3(2)) = (\partial_{00}[\mathbf{v}_1(2)] \quad \partial_{10}[\mathbf{v}_1(2)] \mid \partial_{00}[\mathbf{v}_2(2)] \mid \partial_{00}[\mathbf{v}_3(2)]) \in \mathbb{C}^{q(2) \times m}$$

890 where

$$891 \quad \tilde{\mathbf{V}}_1(2) = (\partial_{00}[\mathbf{v}_1(2)] \quad \partial_{10}[\mathbf{v}_1(2)]) = \begin{pmatrix} 1 & 0 \\ x_1^{(1)} & 1 \\ x_2^{(1)} & 0 \\ x_1^{(1)2} & 2x_1^{(1)} \\ x_1^{(1)}x_2^{(1)} & x_2^{(1)} \\ x_2^{(1)2} & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \in \mathbb{C}^{q(2) \times \mu_1}$$

892 The depth δ_1 of $\mathcal{D}[\mathbf{x}^{(1)}]$ equals $o(\partial_{10}[\mathbf{x}^{(1)}]) = 1$. Take $d^{(1)} = d^{(2)} = 1$ such that
 893 $d^{(1)} + d^{(2)} = 2 \geq 2 = d^*$. The tensor $\mathcal{Y}(1,1) \in \mathbb{C}^{q(1) \times q(1) \times m}$, constructed as shown in
 894 (18), admits the BTD

$$895 \quad (32) \quad \mathcal{Y}(1,1) = \mathcal{G}_1(1,1) \cdot_1 \tilde{\mathbf{V}}_1(1) \cdot_2 \tilde{\mathbf{V}}_1(1) \cdot_3 \mathbf{C}_1(2) \\ + \mathbf{v}_2(1) \otimes \mathbf{v}_2(1) \otimes \mathbf{c}_{2,1}(2) + \mathbf{v}_3(1) \otimes \mathbf{v}_3(1) \otimes \mathbf{c}_{3,1}(2)$$

896 in which

$$897 \quad (\mathbf{G}_1(1,1))_{[2;1,3]} = \left(\begin{array}{cc|cc} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{array} \right).$$

898 First we fit an ($m = 4$)-term CPD using the randomly initialized NLS algorithm
 899 in Tensorlab [40], until the relative change in objective function drops below 10^{-9} or
 900 a maximum of 500 iterations is reached. Figure 4b shows the convergence: it is slow.
 901 A collinearity criterion [31, (2.2)] identifies a group of $\mu_1 = 2$ diverging rank-1 terms
 902 and two linearly independent non-diverging rank-1 terms ($\mu_2 = \mu_3 = 1$).⁶

⁶When the algorithm terminates, the cosine between the vector representations of the two diverging rank-1 terms has become 0.9998 in absolute value.

903 Next we fit a BTM with $m_0 = 3$ and the identified, correct multiplicities μ_k using
 904 NLS with the same stopping criterion. We use the CPD results to initialize the BTM
 905 fitting by means of the SGSD-based procedure in [31, p. 299].

$$906 \quad \tilde{\mathbf{A}}_1(1) = \begin{pmatrix} 1 & 1 \\ 0.0138 & 0.0003 \\ 0 & 0 \end{pmatrix}$$

907 which satisfies $\tilde{\mathbf{A}}_1(1) = \tilde{\mathbf{V}}_1(1)\mathbf{M}_1^{(1)}$ for some nonsingular matrix $\mathbf{M}_1^{(1)}$. From the
 908 last row of $\tilde{\mathbf{A}}_1(1)$ it follows that $x_2^{(1)} = 0$. The value of $x_1^{(1)}$ may be recovered from
 909 $f_2(x_1, x_2) = 0$.

910 Now we repeat the above experiment using Algorithm 1 with the algebraic BTM
 911 computation to find the roots and multiplicities for the system (31).

912 Setting $d^{(1)} = 1$ and $d^{(2)} = 2$ ensures that the prerequisites of Theorem 4.4 are
 913 met and, consequently, the matrices $\mathbf{A}_1(2) \in \mathbb{C}^{3 \times 2}$, $\mathbf{A}_{2,3}(2) \in \mathbb{C}^{3 \times 1}$, $\mathbf{B}_1(2) \in \mathbb{C}^{6 \times 2}$,
 914 and $\mathbf{B}_{2,3}(2) \in \mathbb{C}^{6 \times 1}$ can be readily computed algebraically via a block-diagonalization.
 915 The block-diagonalization already reveals the correct multiplicities $\mu_1 = 2$, $\mu_{2,3} = 1$.
 916 From $\mathbf{B}_1(2)$ the two-fold root $\mathbf{x}^{(1)} = (0, 0)^T$ is retrieved using the generalized ESPRIT
 917 approach (step 9 of subsection 6.1, see also Appendix B.1). The simple roots $\mathbf{x}^{(2,3)}$
 918 are retrieved from scaling the factor vectors of the rank-1 terms of the BTM as in [38,
 919 Algorithm 1]. Let $\mathbf{V}(d) = (\mathbf{v}_1(d) \ \mathbf{v}_2(d) \ \mathbf{v}_3(d)) \in \mathbb{C}^{q(d) \times m_0}$ be the multivariate
 920 Vandermonde matrix of degree $d \geq 1$ associated to the true solutions of the polynomial
 921 system and $\hat{\mathbf{V}}(d)$ the estimated counterpart computed by Algorithm 1. Note that we
 922 do not add derivative columns corresponding to the roots with multiplicities here.
 923 The algebraic BTM based procedure achieves a relative forward error⁷

$$924 \quad \epsilon_{\hat{\mathbf{V}}(1)} = \frac{\|\hat{\mathbf{V}}(1) - \mathbf{V}(1)\|}{\|\mathbf{V}(1)\|}$$

925 of $\mathcal{O}(10^{-14})$ and a residual norm $\|\mathbf{M}(d_0)\mathbf{V}(d_0)\| = \mathcal{O}(10^{-13})$. Not only are these re-
 926 sults significantly more accurate compared to the ones obtained with the NLS-based
 927 BTM computation that we executed before, the algebraic computation is carried out
 928 without the need for iterative procedures and initial guesses (obtained, e.g., by a
 929 preliminary CPD fit). This indicates that the algebraic BTM computation is more
 930 reliable compared to a BTM computation using optimization based methods. Never-
 931 theless, optimization based methods can still be used in cases where some refinement of
 932 the algebraic results is needed, such as for noisy equations (see [38] for an illustration).
 933

934 **7.2. A recursive polynomial root-finding algorithm.** As a numerical illus-
 935 tration of Algorithm 2, consider again the system of $s = 2$ polynomial equations in
 936 $n = 2$ variables [38, Example 3.2]:

$$937 \quad (33) \quad \begin{cases} f_1(x_1, x_2) = -x_1^2 + 2x_1x_2 + x_2^2 + 5x_1 - 3x_2 - 4 = 0 \\ f_2(x_1, x_2) = x_1^2 + 2x_1x_2 + x_2^2 - 1 = 0 \end{cases}$$

938 with $d^{(1)} = d^{(2)} = 2$ and $d^* = 2 + 2 - 2 = 2$. The system has $m = 2 \cdot 2 = 4$ simple
 939 roots $(x_1 \ x_2)^T = (0 \ -1)^T, (1 \ 0)^T, (3 \ -2)^T$ and $(4 \ -5)^T$ ('o' in Figure 5a).

940 From the numerical basis $\mathbf{K}(d) = \mathbf{K}(d^* + 1) = \mathbf{K}(2 + 1)$ for the nullspace of
 941 $\mathbf{M}(d)$ we construct the tensor $\mathcal{Y}(1, 2) \in \mathbb{C}^{3 \times 6 \times 4}$ which has multilinear rank-(3, 4, 4),

⁷Computed using the `cpderr` routine of Tensorlab [40].

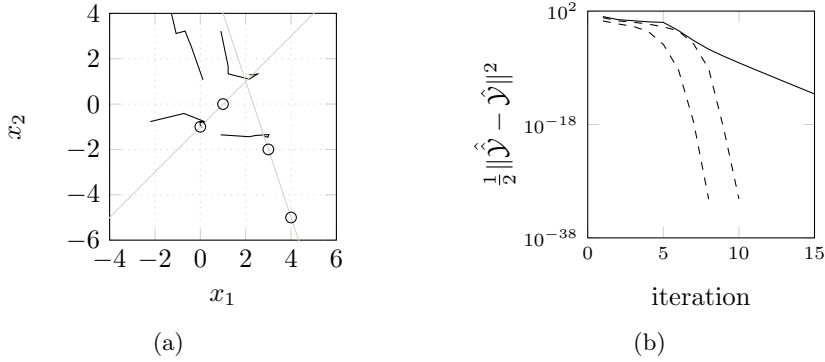

Fig. 5: (a) Convergence of the projected terms in the BTD at the top level in Figure 3 for (33) from a random initialization to subspaces (—) spanned by two roots ‘o’ each. (b) Convergence of an optimization-based NLS type algorithm to fit the BTD (—) and two CPDs in the leaves (- - -) as a function of the iteration step.

942 a MLSVD compression yields $\hat{Y} \in \mathbb{C}^{3 \times 4 \times 4}$. We run Algorithm 2 using NLS and
 943 convergence criterion 10^{-6} for both the CPD in step 2 and the BTD in step 7. As the
 944 initial \hat{Y} has $R = m = 4$, the BTD (top level in Figure 3) directly uses the minimum
 945 sizes $R_1 = R_2 = m/2 = 2$ for the core tensors. To fit the BTD, we randomly initialized
 946 the first factor matrices $\hat{A}_1, \hat{A}_2 \in \mathbb{C}^{3 \times 2}$ for the optimization algorithm (alternatively,
 947 it is also possible to employ an algebraic BTD algorithm as in Section 7.1). Figure 5a
 948 illustrates how the $R_1 = 2$ columns of \hat{A}_1 (first normalized so that $x_0 = 1$ and then
 949 projected as points on the (x_1, x_2) -plane \mathbb{C}^2) converge from their random initialization
 950 to the lower-dimensional subspace (plotted as a gray line (—) in \mathbb{C}^2) spanned by the
 951 columns of

$$952 \quad (\hat{V})_{1,2} = \begin{pmatrix} 1 & 1 \\ x_1^{(1)} & x_1^{(2)} \\ x_2^{(1)} & x_2^{(2)} \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

953 Likewise, the $R_2 = 2$ columns of \hat{A}_2 converge to the subspace (drawn as gray line
 954 (—)) spanned by the two columns of

$$955 \quad (\hat{V})_{3,4} = \begin{pmatrix} 1 & 1 \\ x_1^{(3)} & x_1^{(4)} \\ x_2^{(3)} & x_2^{(4)} \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 3 & 4 \\ -2 & -5 \end{pmatrix}.$$

956 Note that one converged column of \hat{A}_2 is kept outside Figure 5a for visibility. Next,
 957 each CPD in a recursive call of Algorithm 2 (leaf nodes in Figure 3) will converge
 958 within these subspaces to the sought for roots. Figure 5b shows the convergence.
 959 Because there are no multiple roots, there are no diverging rank-1 terms, and conver-
 960 gence is fast.

961 **8. Conclusions.** In [38] we have attempted to show that multilinear algebra
 962 is a convincing framework to formulate and solve 0-dimensional polynomial root-
 963 finding problems. This paper has taken the multilinear algebra framework to the

964 next level. The third-order tensor BTD proposed in [Theorem 4.2](#) is the most general
 965 decomposition in our framework. It incorporates multiple roots, reducing to the CPD
 966 if all roots happen to be simple, it coincides with the triangularization in NPA's
 967 Central Theorem and it is a three-way generalization of the Jordan canonical form,
 968 intimately related to border rank. Furthermore, [Theorem 4.4](#) established uniqueness
 969 properties for the BTD and enables its algebraic computation by means of a block-
 970 diagonalization. Future work might use our findings to formulate a three-way Jordan
 971 form for groups of many diverging rank-1 terms which has so far only been done for
 972 relatively simple cases [\[31, 32\]](#); general expressions are still elusive. We have illustrated
 973 how our BTD-based framework is able to retrieve the roots and their multiplicities
 974 from the null space of the Macaulay matrix. Moreover, we proposed a recursive
 975 method to detect nested structures in the nullspace. This essentially amounts to
 976 splitting a tensor that captures all roots into smaller tensors that capture subsets of
 977 roots, and iterating over such splittings. Future work might also investigate the use of
 978 constrained optimization techniques or prior knowledge to improve the accuracy with
 979 which the roots are found. It may also be interesting to see whether, e.g., clusters of
 980 roots of no interest can be discarded early in the polynomial root-finding procedures.

981 **Appendix A. Proof of [Theorem 3.1](#).** We will need the following lemma.

982 LEMMA A.1. *Let M_1, \dots, M_K be linear transformations on \mathbb{C}^m and let*

$$983 \quad (34) \quad \mathbb{C}^m = V_1 \dot{+} \dots \dot{+} V_R, \quad \dim V_r = \mu_r$$

be a direct sum decomposition of \mathbb{C}^m into subspaces that are invariant for all M_1, \dots, M_K ; ■

$$M_k V_r \subseteq V_r, \quad r = 1, \dots, R, \quad k = 1, \dots, K.$$

984 *Let also*

$$985 \quad (35) \quad \mathbf{M}_k = \text{Blockdiag}(\mathbf{M}_k^{(1)}, \dots, \mathbf{M}_k^{(R)}), \quad \mathbf{M}_k^{(r)} \in \mathbb{C}^{\mu_r \times \mu_r}, \quad r = 1, \dots, R, \quad k = 1, \dots, K$$

986 *be the block-diagonal forms of M_1, \dots, M_K in a basis derived from decomposition [\(34\)](#).*

987 *Assume that*

- 988 1. *there exists a linear combination of M_1, \dots, M_K with matrix representation*
 989 $\mathbf{M} = \text{Blockdiag}(\mathbf{M}^{(1)}, \dots, \mathbf{M}^{(R)})$ *such that the spectra of any two blocks do*
 990 *not intersect;*
- 991 2. *none of the subspaces V_r can be further decomposed into a direct sum of*
 992 *subspaces that are invariant for all transformations M_1, \dots, M_K .*

993 *Then any other decomposition of \mathbb{C}^m into a direct sum of $\tilde{R} \geq R$ subspaces that are*
 994 *invariant for all transformations M_1, \dots, M_K ,*

$$995 \quad (36) \quad \mathbb{C}^m = \tilde{V}_1 \dot{+} \dots \dot{+} \tilde{V}_{\tilde{R}}, \quad \dim \tilde{V}_r = \tilde{\mu}_r,$$

996 *coincides with decomposition [\(34\)](#) up to permutation of terms, that is, $\tilde{V}_1 = V_{\pi(1)}, \dots, \tilde{V}_{\tilde{R}} =$ ■*
 997 $V_{\pi(R)}$ *for some permutation π of $\{1, \dots, R\}$. In particular, it necessarily holds that*
 998 $\tilde{R} = R$ *and that $\tilde{\mu}_1 = \mu_{\pi(1)}, \dots, \tilde{\mu}_R = \mu_{\pi(R)}$.*

999 *Proof.* Let subspace W be invariant for all transformations M_1, \dots, M_K . Then
 1000 W is also invariant for the transformation M . Hence, by assumption 1 and [\[18,](#)
 1001 [Theorem 2.1.5\]](#), $W = W_1 \dot{+} \dots \dot{+} W_R$, where the subspaces $W_1 \subseteq V_1, \dots, W_R \subseteq V_R$
 1002 are invariant for M . Moreover, since W is invariant for all M_1, \dots, M_K and [\(34\)](#) is a
 1003 direct sum decomposition, it follows that the subspaces W_1, \dots, W_R are also invariant

1004 for all transformations M_1, \dots, M_K . Applying this result to the subspaces $\tilde{V}_1, \dots, \tilde{V}_{\tilde{R}}$
 1005 in decomposition (36) we obtain that

$$1006 \quad (37) \quad \tilde{V}_1 = W_{11} \dot{+} \dots \dot{+} W_{1R}, \dots, \tilde{V}_{\tilde{R}} = W_{\tilde{R}1} \dot{+} \dots \dot{+} W_{\tilde{R}R},$$

1007 where the subspaces

$$1008 \quad (38) \quad W_{11}, W_{21}, \dots, W_{\tilde{R}1} \subseteq V_1, \dots, W_{1R}, W_{2R}, \dots, W_{\tilde{R}R} \subseteq V_R$$

1009 are invariant for all transformations M_1, \dots, M_K . Now from (34), (36), (37), and (38)
 1010 we obtain that

$$1011 \quad (39) \quad V_1 \dot{+} \dots \dot{+} V_R = \mathbb{C}^I = \tilde{V}_1 \dot{+} \dots \dot{+} \tilde{V}_{\tilde{R}} = (W_{11} \dot{+} \dots \dot{+} W_{1R}) \dot{+} \dots \dot{+} (W_{\tilde{R}1} \dot{+} \dots \dot{+} W_{\tilde{R}R}) =$$

$$1012 \quad (W_{11} \dot{+} W_{21} \dot{+} \dots \dot{+} W_{\tilde{R}1}) \dot{+} \dots \dot{+} (W_{1R} \dot{+} W_{2R} \dot{+} \dots \dot{+} W_{\tilde{R}R}) \subseteq V_1 \dot{+} \dots \dot{+} V_R.$$

1014

1015 Hence $V_r = W_{1r} \dot{+} W_{2r} \dot{+} \dots \dot{+} W_{\tilde{R}r}$, $r = 1, \dots, R$. By assumption 2, this is possible only
 1016 if one of the subspaces $W_{1r}, W_{2r}, \dots, W_{\tilde{R}r}$ coincides with V_r and the other subspaces
 1017 are zero. This easily implies the statement of the lemma. \square

1018 *Proof of Theorem 3.1.* Since the matrix \mathbf{B} has full column rank, it is sufficient
 1019 to prove that for any decomposition of \mathcal{T} into a sum of indecomposable tensors the
 1020 blocks of the matrix in the second mode can be permuted so that their column spaces
 1021 coincide with the column spaces of the blocks $\mathbf{B}_1, \dots, \mathbf{B}_R$. To prove the uniqueness of
 1022 the column spaces $\text{col}(\mathbf{B}_1), \dots, \text{col}(\mathbf{B}_R)$ we will use Lemma A.1. In our derivation we
 1023 assume without loss of generality that the matrix \mathbf{B} is square, so $\mu_1 + \dots + \mu_R = m$
 1024 and $\mathbf{B} \in \mathbb{C}^{m \times m}$.

1025 *Step 1: Reduction to Lemma A.1.* For any $\mathbf{f} \in \mathbb{C}^{I_1}$ we have that

$$1026 \quad (40) \quad \mathcal{T} \cdot_1 \mathbf{f}^T = \mathbf{B} \cdot \text{Blockdiag}(\mathcal{G}_1 \cdot_1 (\mathbf{f}^T \mathbf{A}_1), \dots, \mathcal{G}_R \cdot_1 (\mathbf{f}^T \mathbf{A}_R)) \cdot \mathbf{C}^T,$$

1029 where we identify the one-slice tensors $\mathcal{T} \cdot_1 \mathbf{f}^T \in \mathbb{C}^{1 \times m \times m}$ and $\mathcal{G}_1 \cdot_1 (\mathbf{f}^T \mathbf{A}_1) \in$
 1030 $\mathbb{C}^{1 \times \mu_1 \times \mu_1}, \dots, \mathcal{G}_R \cdot_1 (\mathbf{f}^T \mathbf{A}_R) \in \mathbb{C}^{1 \times \mu_R \times \mu_R}$ with matrices. Since the first horizontal
 1031 slice of \mathcal{G}_r is the identity matrix and the other frontal slices are strictly upper trian-
 1032 gular, we have that

$$1033 \quad (41) \quad \mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r) \text{ is the sum of } \mathbf{f}^T \mathbf{A}_r(:, 1) \mathbf{I}_{\mu_r} \text{ and a strictly upper triangular matrix.}$$

1034 Since, by (6), the first columns of the matrices $\mathbf{A}_1, \dots, \mathbf{A}_R$ are nonzero, it easily
 1035 follows that for generic $\mathbf{f} \in \mathbb{C}^{I_1}$ all values $\mathbf{f}^T \mathbf{A}_1(:, 1), \dots, \mathbf{f}^T \mathbf{A}_R(:, 1)$ are nonzero.
 1036 Hence, by (40) and (41), the $m \times m$ matrix $\mathcal{T} \cdot_1 \mathbf{f}^T$ is nonsingular for generic $\mathbf{f} \in \mathbb{C}^{I_1}$.
 1037 Hence for $k = 1, \dots, I_1$ we have that

$$1038 \quad (42) \quad \mathcal{T}(k, :, :)(\mathcal{T} \cdot_1 \mathbf{f}^T)^{-1} = \mathbf{B} \cdot \text{Blockdiag}(\mathcal{G}_1 \cdot_1 (\mathbf{A}_1(k, :))(\mathcal{G}_1 \cdot_1 (\mathbf{f}^T \mathbf{A}_1))^{-1}, \dots, \mathcal{G}_R \cdot_1 (\mathbf{A}_R(k, :))(\mathcal{G}_R \cdot_1 (\mathbf{f}^T \mathbf{A}_R))^{-1}) \cdot \mathbf{B}^{-1}.$$

1042 Thus, the matrices $\mathcal{T}(k, :, :)(\mathcal{T} \cdot_1 \mathbf{f}^T)^{-1}$ can be simultaneously reduced to block di-
 1043 agonal form by a similarity transform. This means that the column spaces of the
 1044 blocks $\mathbf{B}_1, \dots, \mathbf{B}_{m_0}$ are invariant for all matrices $\mathcal{T}(1, :, :)(\mathcal{T} \cdot_1 \mathbf{f}^T)^{-1}, \dots, \mathcal{T}(I_1, :, :$

1045 $(\mathcal{T} \cdot_1 \mathbf{f}^T)^{-1}$ and that the whole space \mathbb{C}^m can be decomposed into the direct sum of
 1046 $\text{col}(\mathbf{B}_1), \dots, \text{col}(\mathbf{B}_R)$: $\mathbb{C}^m = \text{col}(\mathbf{B}_1) \dot{+} \dots \dot{+} \text{col}(\mathbf{B}_R)$.

1047 *Step 2.* By Step 1, any BTD $\mathcal{T} = \sum_{r=1}^{\tilde{R}} \left[\tilde{\mathcal{G}}_r; \tilde{\mathbf{A}}_r, \tilde{\mathbf{B}}_r, \tilde{\mathbf{C}}_r \right]$ with nonsingular $\tilde{\mathbf{B}} \stackrel{\text{def}}{=} \tilde{\mathbf{B}}_1 \dots \tilde{\mathbf{B}}_{\tilde{R}}$ and $\tilde{\mathbf{C}} \stackrel{\text{def}}{=} (\tilde{\mathbf{C}}_1 \dots \tilde{\mathbf{C}}_{\tilde{R}})$ generates a decomposition of \mathbb{C}^m into a
 1048 direct sum of $\text{col}(\tilde{\mathbf{B}}_1), \dots, \text{col}(\tilde{\mathbf{B}}_{\tilde{R}})$. To show that all such decomposition coincide up
 1049 to permutation of the terms with the decomposition $\mathbb{C}^m = \text{col}(\mathbf{B}_1) \dot{+} \dots \dot{+} \text{col}(\mathbf{B}_R)$,
 1050 we show that the assumptions in Lemma A.1 hold for $K = I_1$, $V_r = \text{col}(\mathbf{B}_r)$, and
 1051 (43)

$$1052 \quad \mathbf{M}_k = \text{Blockdiag}(\mathbf{M}_k^{(1)}, \dots, \mathbf{M}_k^{(R)}) \text{ with } \mathbf{M}_k^{(r)} = (\mathcal{G}_r \cdot_1 (\mathbf{A}_r(k, :))) (\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1}.$$

1053 *Assumption 1.* Let $\mathbf{h} \in \mathbb{C}^K$ and $\mathbf{M} \stackrel{\text{def}}{=} h_1 \mathbf{M}_1 + \dots + h_K \mathbf{M}_K$. Then, by
 1054 (43), the r th diagonal block of \mathbf{M} is the sum of $(\mathbf{h}^T \mathbf{A}_r(:, 1)) (\mathbf{f}^T \mathbf{A}_r(:, 1))^{-1} \mathbf{I}_{\mu_r}$ and
 1055 a strictly upper triangular matrix. Hence, the diagonal blocks of \mathbf{M} have one-point
 1056 spectra $(\mathbf{h}^T \mathbf{A}_1(:, 1)) (\mathbf{f}^T \mathbf{A}_1(:, 1))^{-1}, \dots, (\mathbf{h}^T \mathbf{A}_R(:, 1)) (\mathbf{f}^T \mathbf{A}_R(:, 1))^{-1}$. We show that
 1057 there exists a vector \mathbf{h} such that the values $(\mathbf{h}^T \mathbf{A}_1(:, 1)) (\mathbf{f}^T \mathbf{A}_1(:, 1))^{-1}, \dots, (\mathbf{h}^T \mathbf{A}_R(:, 1)) (\mathbf{f}^T \mathbf{A}_R(:, 1))^{-1}$
 1058 are distinct. Indeed, if $(\mathbf{h}^T \mathbf{A}_{r_1}(:, 1)) (\mathbf{f}^T \mathbf{A}_{r_1}(:, 1))^{-1} = (\mathbf{h}^T \mathbf{A}_{r_2}(:, 1)) (\mathbf{f}^T \mathbf{A}_{r_2}(:, 1))^{-1}$, then easy algebraic manipulations imply that

$$1060 \quad (44) \quad \mathbf{h}^T (\mathbf{f}^T \mathbf{A}_{r_2}(:, 1)) \mathbf{A}_{r_1}(:, 1) = \mathbf{h}^T (\mathbf{f}^T \mathbf{A}_{r_1}(:, 1)) \mathbf{A}_{r_2}(:, 1).$$

1061 Thus, (44) holds only for vectors \mathbf{h} that are orthogonal to the vector $((\mathbf{f}^T \mathbf{A}_{r_2}(:, 1)) \mathbf{A}_{r_1}(:, 1) - (\mathbf{f}^T \mathbf{A}_{r_1}(:, 1)) \mathbf{A}_{r_2}(:, 1))^*$, which, because of the generic choice of \mathbf{f} in
 1062 Step 1 and by assumption (6), is nonzero. Hence, the values $(\mathbf{h}^T \mathbf{A}_1(:, 1)) (\mathbf{f}^T \mathbf{A}_1(:, 1))^{-1}, \dots, (\mathbf{h}^T \mathbf{A}_R(:, 1)) (\mathbf{f}^T \mathbf{A}_R(:, 1))^{-1}$ are distinct for any vector \mathbf{h} that is not or-
 1063 thogonal to any of the $\frac{R(R-1)}{2}$ vectors $((\mathbf{f}^T \mathbf{A}_{r_2}(:, 1)) \mathbf{A}_{r_1}(:, 1) - (\mathbf{f}^T \mathbf{A}_{r_1}(:, 1)) \mathbf{A}_{r_2}(:, 1))^*$,
 1064 $1 \leq r_1 < r_2 \leq R$.

1065 *Assumption 2.* Since the matrix \mathbf{A}_r has full column rank, its row space is
 1066 equal to \mathbb{C}^{μ_r} . Hence the subspace spanned by the matrices $\mathbf{M}_1^{(r)}, \dots, \mathbf{M}_{\mu_r}^{(r)}$ coin-
 1067 cides with the subspace spanned by the nonsingular upper triangular matrix $\mathbf{S}_1 \stackrel{\text{def}}{=} (\mathcal{G}_r \cdot_1 (\mathbf{I}_{\mu_r}(1, :))) (\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1} = (\mathcal{G}_r(1, :, :)) (\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1}$ and the $\mu_r - 1$ strictly
 1068 upper triangular matrices $\mathbf{S}_{l+1} \stackrel{\text{def}}{=} (\mathcal{G}_r \cdot_1 (\mathbf{I}_{\mu_r}(l+1, :))) (\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1} = (\mathcal{G}_r(l+1, :, :)) (\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1}$, $l = 1, \dots, \mu_r - 1$. To prove that the subspace \mathbb{C}^{μ_r} cannot be decom-
 1069 posed into a direct sum of subspaces that are invariant for all matrices $\mathbf{M}_1^{(r)}, \dots, \mathbf{M}_{\mu_r}^{(r)}$,
 1070 we prove a stronger statement: the subspace \mathbb{C}^{μ_r} cannot be decomposed into a direct
 1071 sum of subspaces that are invariant for all matrices $\mathbf{S}_2, \dots, \mathbf{S}_{\mu_R}$. Since $\mathbf{S}_2, \dots, \mathbf{S}_{\mu_R}$ are
 1072 nilpotent matrices, it is sufficient to prove that the common null space of $\mathbf{S}_2, \dots, \mathbf{S}_{\mu_R}$
 1073 is trivial, i.e., is spanned by the vector $\mathbf{I}_{\mu_r}(:, 1)$. Let \mathbf{u} be a nonzero vector such that
 1074 $\mathbf{S}_2 \mathbf{u} = \dots = \mathbf{S}_{\mu_R} \mathbf{u} = \mathbf{0}$. Since $\mathcal{G}_r(:, 1, :) = \mathbf{I}_{\mu_r}$, it follows that the first rows of the
 1075 matrices $\mathbf{S}_2, \dots, \mathbf{S}_{\mu_r}$ are proportional, respectively, to the 2nd, 3rd, \dots , μ_r th row of
 1076 the matrix $(\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1}$. Hence, the identities $\mathbf{S}_2 \mathbf{u} = \dots = \mathbf{S}_{\mu_R} \mathbf{u} = \mathbf{0}$ imply that
 1077 the last $\mu_r - 1$ entries of the vector $(\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1} \mathbf{u}$ are zero. Since the matrix
 1078 $(\mathcal{G}_r \cdot_1 (\mathbf{f}^T \mathbf{A}_r))^{-1}$ is nonsingular and upper triangular, it follows that the last $\mu_r - 1$
 1079 entries of the vector \mathbf{u} are zero as well. \square

1084 **Appendix B. Derivation of Theorem 4.2.** In this section we derive the
 1085 BTD structure in Theorem 4.2. Throughout this derivation we will make frequent
 1086 use of the following Definition B.1 and Lemma B.3.

1087 DEFINITION B.1. [6, Definition 1] Let the linear transformation ϕ_j be defined by

$$1088 \quad \phi_j(\partial_{j_1 \dots j_n}[\mathbf{z}](f)) = \begin{cases} \partial_{j_1 \dots j_{j-1}, j_{j+1} \dots j_n}[\mathbf{z}](f), & j_j \neq 0 \\ 0\text{-functional}, & j_j = 0. \end{cases}$$

1089 Given a system of polynomial equations \mathcal{F} and a μ_k -fold root \mathbf{z} , the dual subspaces
1090 $\mathcal{D}_t[\mathbf{z}](\mathcal{F})$ are the strictly enlarging sets $\mathcal{D}_0[\mathbf{z}](\mathcal{F}) = \text{span}(\partial_0[\mathbf{z}])$ and

$$1091 \quad \mathcal{D}_t[\mathbf{z}](\mathcal{F}) = \text{span} \left(\left\{ c = \sum_{|\mathbf{j}| \leq t} \beta_j \partial_j[\mathbf{z}](f) \mid c(\mathcal{F}) = \{0\} \ \& \ \forall j : \phi_j(c) \in \mathcal{D}_{t-1}[\mathbf{z}](\mathcal{F}) \right\} \right).$$

1092 If $\mathcal{D}_{\delta+1}[\mathbf{z}] = \mathcal{D}_\delta[\mathbf{z}]$, then the vector space $\mathcal{D}_\delta[\mathbf{z}] = \mathcal{D}[\mathbf{z}]$ is called the dual space of
1093 the system \mathcal{F} at \mathbf{z} and δ is called its depth. The dual space reveals the multiplicity
1094 structure of the root \mathbf{z} ; its dimension equals the multiplicity μ_k .

1095 EXAMPLE B.2. Consider again example 3.5 with $f \in \mathcal{C}^2$, a four-fold root $\mathbf{z} \in$
1096 \mathcal{C}^2 with $\delta = 2$, and the differential functionals $c_{10} = \partial_{00}$, $c_{11} = \partial_{10}$, $c_{12} = \partial_{01}$,
1097 $c_{13} = (2\partial_{20} + \partial_{11})$. Obviously, $c_{10} \in \mathcal{D}_0[\mathbf{z}] \subset \mathcal{D}_2[\mathbf{z}]$. Since $\phi_1(c_{11}) = \phi_1(\partial_{10}) = \partial_{00}$,
1098 $\phi_2(c_{11}) = 0$ we have $c_{11} \in \mathcal{D}_1[\mathbf{z}] \subset \mathcal{D}_2[\mathbf{z}]$ and likewise for c_{12} . For c_{13} we have
1099 that $\phi_1(c_{13}) = 2\partial_{10} + \partial_{01} \in \mathcal{D}_1[\mathbf{z}]$ and $\phi_2(c_{13}) = \partial_{10} \in \mathcal{D}_1[\mathbf{z}]$ so that $c_{13} \in \mathcal{D}_2[\mathbf{z}]$.
1100 Due to the nested structure of \mathcal{D} , it also holds $\phi_i(\phi_j(c_{kl})) \in \mathcal{D}$, $i, j = 1, 2$. Indeed,
1101 we have, e.g., $\phi_1(\phi_1(c_{13})) = 2\partial_{00} \in \mathcal{D}_2[\mathbf{z}]$ as well as $\phi_2(\phi_1(c_{13})) = \partial_{00} \in \mathcal{D}_2[\mathbf{z}]$,
1102 $\phi_2(\phi_2(c_{13})) = 0 \in \mathcal{D}_2[\mathbf{z}]$.

1103 We use the Leibniz formula (generalization of the product rule).

1104 LEMMA B.3. Let $p, q \in \mathcal{C}^n$. Then for $\mathbf{k} \in \mathbb{N}^n$

$$1105 \quad \partial_{\mathbf{k}}[p \cdot q] = \sum_{\mathbf{0} \leq \mathbf{j} \leq \mathbf{k}} \partial_{\mathbf{j}}[p] \cdot \partial_{\mathbf{k}-\mathbf{j}}[q].$$

1106

1107 With these prerequisites we are now ready to establish the BTD (19) in Theorem 4.2.
1108 We will do so in two steps: at first we generalize the multiplicative shift structure
1109 for multivariate Vandermonde matrices, that was used in [38] for the case of only
1110 simple roots, to confluent multivariate Vandermonde matrices and roots with multi-
1111 plicities greater than one (Section B.1). This result is afterwards used to establish
1112 the BTD (19) starting from the nullspace of the Macaulay matrix (Section B.2).
1113 Throughout the whole derivation, examples will illustrate main intermediate steps.

1114 **B.1. First step: Generalization of the multiplicative shift structure.**

1115 We consider the confluent multivariate Vandermonde matrix

$$1116 \quad (45a) \quad \tilde{\mathbf{V}}(d) = (\tilde{\mathbf{V}}_1(d) \quad \dots \quad \tilde{\mathbf{V}}_{m_0}(d)) \in \mathbb{C}^{q(d) \times m}$$

1117 associated to a 0-dimensional polynomial system \mathcal{F} with $m_0 \leq m$ distinct roots. Each
1118 block $\tilde{\mathbf{V}}_k(d)$, $k = 1 : m_0$ is of the form

$$1119 \quad (45b) \quad \tilde{\mathbf{V}}_k(d) = (\overbrace{c_{k0}[\mathbf{v}(d)]}^{\text{order 0}} \mid \overbrace{c_{k1}[\mathbf{v}(d)] \quad \dots \mid \dots}^{\text{order 1}} \mid \dots \mid \overbrace{c_{k, \mu_k-1}[\mathbf{v}(d)]}^{\text{order } \delta_k}) \in \mathbb{C}^{q(d) \times \mu_k}$$

1120 and contains the μ_k unique differential functional columns $c_{kl}[\mathbf{v}] \in \mathcal{D}[\mathbf{z}_k]$ which we
1121 assume w.l.o.g. to be ordered increasingly regarding the differentiation order of the
1122 differential functionals.

1123 LEMMA B.4. Let $\tilde{\mathbf{V}}(d)$ be as in (45) with $d = d^{(1)} + d^{(2)} \geq d^*$, $d^{(1)} \geq 1$. Let further
 1124 $\bar{\mathbf{S}}^{(0)} \in \mathbb{C}^{q(d^{(2)}) \times q(d)}$ select the rows of $\tilde{\mathbf{V}}(d)$ associated to the monomials of degree 0 to
 1125 $d^{(2)}$ and let $\bar{\mathbf{S}}^{(j)} \in \mathbb{C}^{q(d^{(2)}) \times q(d)}$ select the rows onto which these monomials are mapped
 1126 after a multiplication with the $(j+1)$ th monomial $\mathbf{x}^{\alpha_j} = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$, $\alpha_j \in \mathbb{N}^n$ with
 1127 $|\alpha_j| \leq d^{(1)}$.

1128 Then the generalized multiplicative shift structure / ESPRIT-type relation

$$1129 \quad (46) \quad \bar{\mathbf{S}}^{(j)}(d^{(2)})\tilde{\mathbf{V}}_k(d) = \bar{\mathbf{S}}^{(0)}(d^{(2)})\tilde{\mathbf{V}}_k(d)\mathbf{J}_k^{(j)}, \quad 0 \leq j \leq q(d^{(1)}) - 1, \quad k = 1 : m_0$$

1131 holds, where $\mathbf{J}_k^{(j)} = \mathbf{x}^{\alpha_j}\mathbf{I}_{\mu_k} + \mathbf{N}_k^{(j)} \in \mathbb{C}^{\mu_k \times \mu_k}$ with $\mathbf{N}_k^{(j)}$ strictly upper triangular. For
 1132 all $0 \leq i, j$ the upper triangular matrices $\mathbf{J}_k^{(i)}, \mathbf{J}_k^{(j)}$ commute. Moreover, for the $(j+1)$ th
 1133 monomial $\mathbf{x}^{\alpha} = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ the associated upper triangular matrix $\mathbf{J}_k^{(j)}$ in (46) is given
 1134 by

$$1135 \quad (47) \quad \mathbf{J}_k^{(j)} = (\mathbf{J}_k^{(1)})^{\alpha_1} \cdots (\mathbf{J}_k^{(n)})^{\alpha_n}$$

1137 so that all $\mathbf{J}_k^{(j)}$ are defined by the n upper triangular matrices $\mathbf{J}_k^{(1)}, \dots, \mathbf{J}_k^{(n)}$ associated
 1138 to the monomials x_1, \dots, x_n of degree one.

1139 *Proof.* (46) holds trivially for $j = 0$ with $\mathbf{J}_k^{(0)} = \mathbf{I}_{\mu_k}$. We begin the derivation
 1140 with shifts by the degree one monomials x_j , $j = 1 : n$ (i.e., $\alpha_j = \mathbf{e}_j$, $|\alpha_j| = 1$).
 1141 Only the first columns $c_{k0}[\mathbf{v}_k(d)] = \partial_{00}[\mathbf{v}_k(d)] = \mathbf{v}_k(d) = \mathbf{v}_k$ are genuine multivariate
 1142 Vandermonde vectors for which the simple multiplicative shift invariance holds:

$$1143 \quad (48a) \quad \bar{\mathbf{S}}^{(j)}(d^{(2)})\mathbf{v}_k = x_j \cdot \bar{\mathbf{S}}^{(0)}(d^{(2)})\mathbf{v}_k, \quad j = 1 : n,$$

1144 whereas by linearity of c_{kl} and the multiplication by $\bar{\mathbf{S}}^{(j)}(d^{(2)})$, we have for the re-
 1145 maining columns

$$1146 \quad (48b) \quad \bar{\mathbf{S}}^{(j)}(d^{(2)})c_{kl}[\mathbf{v}_k] = \bar{\mathbf{S}}^{(0)}(d^{(2)})c_{kl}[x_j\mathbf{v}_k], \quad j = 1 : n.$$

1147 With the help of Definition B.1, Lemma B.3 it holds for the application of $c_{kl} =$
 1148 $\sum_{\mathbf{r}} \beta_{\mathbf{r}} \partial_{\mathbf{r}}$ to $x_j\mathbf{v}_k$ for $l = 1 : \mu_k - 1$:

$$1149 \quad c_{kl}[x_j\mathbf{v}_k] = \sum_{\mathbf{r}} \beta_{\mathbf{r}} \partial_{\mathbf{r}}[x_j\mathbf{v}_k] = \sum_{\mathbf{r}} \beta_{\mathbf{r}} \sum_{\mathbf{0} \leq \mathbf{i} \leq \mathbf{r}} \partial_{\mathbf{i}}[x_j] \partial_{\mathbf{r}-\mathbf{i}}[\mathbf{v}_k] = \sum_{\mathbf{r}} \beta_{\mathbf{r}} \sum_{|\mathbf{i}|=0}^1 \partial_{\mathbf{i}}[x_j] \partial_{\mathbf{r}-\mathbf{i}}[\mathbf{v}_k]$$

$$1150 \quad = \sum_{\mathbf{r}} \beta_{\mathbf{r}} (x_j \partial_{\mathbf{r}}[\mathbf{v}_k] + \partial_{\mathbf{r}-\mathbf{e}_j}[\mathbf{v}_k]) = x_j c_{kl}[\mathbf{v}_k] + \phi_j(c_{kl})[\mathbf{v}_k].$$

1152 Now let $1 \leq t \leq \delta_k$ be the differential order of c_{kl} . Since $c_{kl} \in \mathcal{D}_t[\mathbf{z}_k] \subseteq \mathcal{D}[\mathbf{z}_k]$,
 1153 it holds by Definition B.1 that $\phi_j(c_{kl}) \in \mathcal{D}_{t-1} \subset \mathcal{D}[\mathbf{z}_k]$ which means $\phi_j(c_{kl})$ can be
 1154 expressed as linear combination of differential functionals from $\mathcal{D}[\mathbf{z}_k]$ of order less than
 1155 t . In other words, $\phi_j(c_{kl})[\mathbf{v}_k]$ can be expressed as linear combinations of columns of
 1156 $\tilde{\mathbf{V}}_k(:, 1 : l')$, $l' < l$ and whose differential order is strictly smaller than t . Hence,

$$1157 \quad c_{kl}[x_j\mathbf{v}_k] = x_j c_{kl}[\mathbf{v}_k] + \sum_{l' < l} \gamma_{l'l} c_{kl'}[\mathbf{v}_k] \quad \text{for some } \gamma_{l'l} \in \mathbb{C}$$

$$1158 \quad (49) \quad = \tilde{\mathbf{V}}_k \mathbf{J}_k^{(j)}(:, l+1), \quad \mathbf{J}_k^{(j)}(:, l+1) = \begin{pmatrix} \gamma_{0l} \\ \vdots \\ \gamma_{l-1,l} \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \quad l = 1 : \mu_k - 1.$$

1159

1160 Together with (48a), deploying the relations (49) in all μ_k columns in (48b) yields

$$1161 \quad \bar{\mathbf{S}}^{(j)}(d^{(2)})\tilde{\mathbf{V}}_k(d) = \bar{\mathbf{S}}^{(0)}(d^{(2)})\tilde{\mathbf{V}}_k(d)\mathbf{J}_k^{(j)}$$

1163 with $\mathbf{J}_k^{(j)} = x_j\mathbf{I}_{\mu_k} + \mathbf{N}_k^{(j)} \in \mathbb{C}^{\mu_k \times \mu_k}$ with the γ 's in the strictly upper triangular part
1164 $\mathbf{N}_k^{(j)}$.

1165 This relation can be extended towards shifts with higher degree monomials, i.e.,
1166 $\mathbf{x}^{\alpha_j} \cdot \mathbf{v}_k$ with $|\alpha_j| > 1$. It similarly holds $\bar{\mathbf{S}}^{(j)}(d^{(2)})\mathbf{v}_k = \mathbf{x}^{\alpha_j} \cdot \bar{\mathbf{S}}^{(0)}(d^{(2)})\mathbf{v}_k$ for the first
1167 columns. The application of the functionals yields

$$1168 \quad (50) \quad c_{kl}[\mathbf{x}^{\alpha_j} \mathbf{v}_k] = \sum_{\mathbf{r}} \beta_{\mathbf{r}} \sum_{\mathbf{0} \leq \mathbf{i} \leq \mathbf{r}} \partial_{\mathbf{i}}[\mathbf{x}^{\alpha_j}] \partial_{\mathbf{r}-\mathbf{i}}[\mathbf{v}_k] = \sum_{\mathbf{r}} \beta_{\mathbf{r}} \sum_{\mathbf{i}=0}^{\min(t, |\alpha_j|)} \partial_{\mathbf{i}}[\mathbf{x}^{\alpha_j}] \phi^{\mathbf{i}}(\partial_{\mathbf{r}})[\mathbf{v}_k],$$

1170 where we again used Definition B.1, Lemma B.3 and introduced the notation $\phi^{\mathbf{i}} \stackrel{\text{def}}{=} \phi_1^{i_1}(\phi_2^{i_2}(\dots \phi_n^{i_n}))$ and $\phi_j^{i_j} \stackrel{\text{def}}{=} \phi_j(\phi_j(\dots \phi_j))$ (i_j -fold application of ϕ_j). Because of the
1171 nested structure of the dual space $\mathcal{D}[\mathbf{z}_k]$ it still holds that $\phi^{\mathbf{i}}(c_{kl}) \in \mathcal{D}_{\max(0, t-|\mathbf{i}|)}[\mathbf{z}_k] \subset$
1172 $\mathcal{D}[\mathbf{z}_k]$. Hence, (50) can be written as

$$1174 \quad c_{kl}[\mathbf{x}^{\alpha_j} \mathbf{v}_k] = \mathbf{x}^{\alpha_j} c_{kl}[\mathbf{v}_k] + \sum_{l' < l} \gamma_{l'l}(\mathbf{x}) c_{kl'}[\mathbf{v}_k], \quad \text{for some } \gamma_{l'l}(\mathbf{x}) \in \mathcal{C}^{|\alpha_j|-1}$$

$$1175 \quad = \tilde{\mathbf{V}}_k \begin{pmatrix} \gamma_{0l}(\mathbf{x}) \\ \vdots \\ \gamma_{l-1, l}(\mathbf{x}) \\ \mathbf{x}^{\alpha_j} \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \quad l = 1 : \mu_k - 1,$$

1177 so that (46) also holds for all $j \leq q(d^{(1)}) - 1$, where $j > n$ indicates a multiplicative
1178 shift with the $(j+1)$ th monomial in the chosen monomial ordering. The associated
1179 upper triangular matrices $\mathbf{J}_k^{(j)}$ will have strict upper triangular parts that may depend
1180 on the values of $x_1^{(k)}, \dots, x_n^{(k)}$.

1181 We now establish (47) for the sake of presentation for the shift x_j^2 , i.e., $\alpha = 2\mathbf{e}_j$.
1182 We proceed through the steps in (50) in a slightly different way (but again making
1183 use of Definition B.1, Lemma B.3):

$$1184 \quad c_{kl}[x_j^2 \mathbf{v}_k] = c_{kl}[x_j(x_j \mathbf{v}_k)] = \sum_{\mathbf{r}} \beta_{\mathbf{r}} \sum_{\mathbf{0} \leq \mathbf{i} \leq \mathbf{r}} \partial_{\mathbf{i}}[x_j] \partial_{\mathbf{r}-\mathbf{i}}[x_j \mathbf{v}_k]$$

$$1185 \quad = \sum_{\mathbf{r}} \beta_{\mathbf{r}} (x_j \partial_{\mathbf{r}}[x_j \mathbf{v}_k] + \partial_{\mathbf{r}-\mathbf{e}_j}[x_j \mathbf{v}_k]) = x_j c_{kl}[x_j \mathbf{v}_k] + \phi_j c_{kl}[x_j \mathbf{v}_k]$$

$$1186 \quad = x_j \left(x_j c_{kl}[\mathbf{v}_k] + \sum_{l' < l} \gamma_{l'l} c_{kl'}[\mathbf{v}_k] \right) + \phi_j \left(x_j c_{kl}[\mathbf{v}_k] + \sum_{l' < l} \gamma_{l'l} c_{kl'}[\mathbf{v}_k] \right)$$

$$1187 \quad (51) \quad = x_j \tilde{\mathbf{V}}_k \mathbf{J}_k^{(j)}(:, l+1) + x_j \tilde{\mathbf{V}}_k(:, 1:l) \mathbf{J}_k^{(j)}(1:l, l+1) + \sum_{l' < l} \gamma_{l'l} \phi_j(c_{kl'})[\mathbf{v}_k],$$

1189 where we used (49). For the rightmost term in (51), recall that $c_{kl'} \in \mathcal{D}_{t-1}[\mathbf{z}_k]$ if
1190 $1 \leq t \leq \delta_k$ is the differentiation order of c_{kl} . Thus, by the nested structure of $\mathcal{D}[\mathbf{z}_k]$,
1191 $\phi_j(c_{kl'}) \in \mathcal{D}_{\max(0, t-2)}[\mathbf{z}_k]$ so that $\phi_j(c_{kl'}) = \sum_{l'' < l'} \gamma_{l''l'} c_{kl''}$. Consequently,

$$1192 \quad \sum_{l' < l} \gamma_{l'l} \phi_j(c_{kl'})[\mathbf{v}_k] = \sum_{l' < l} \gamma_{l'l} \sum_{l'' < l'} \gamma_{l''l'} c_{kl''}[\mathbf{v}_k] = \sum_{l' < l} \gamma_{l'l} \tilde{\mathbf{V}}_k \mathbf{J}_k^{(j)}(:, l'+1)$$

1193

1194 and, by recalling that $\mathbf{J}_k^{(j)}(l+1, l+1) = \gamma_l = x_j$ for $l = 0 : \mu_k - 1$, we can write (51)
1195 as

(52)

$$1196 \quad c_{kl}[x_j^2 \mathbf{v}_k] = \tilde{\mathbf{V}}_k \left(\gamma_l \mathbf{J}_k^{(j)}(:, l+1) + \gamma_l \mathbf{J}_k^{(j)}(1:l, l+1) + \mathbf{J}_k^{(j)}(:, 1:l'+1) \mathbf{J}_k^{(j)}(:, l+1) \right)$$

$$1197 \quad (53) \quad = \tilde{\mathbf{V}}_k \mathbf{J}_k^{(j)} \mathbf{J}_k^{(j)}(:, l+1).$$

1199 We identify $\mathbf{J}_k^{(j)} \mathbf{J}_k^{(j)}(:, l+1)$ as the $(l+1)$ th column of $\mathbf{J}_k^{(j)2}$ and using (52) for $l =$
1200 $0 : \mu_k - 1$ yields (47) for quadratic shifting monomials x_j^2 . The above reasoning can
1201 be extended first towards higher degree pure monomials $x_j^{\alpha_j}$, $\alpha_j > 2$ and finally to
1202 general monomials $x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ which establishes (47). \square

1203 **EXAMPLE B.5.** Consider again example 3.5 with the differential functionals $c_{10} =$
1204 ∂_{00} , $c_{11} = \partial_{10}$, $c_{12} = \partial_{01}$, $c_{13} = (2\partial_{20} + \partial_{11})$ and, thus, $\tilde{\mathbf{V}}_1(d) = (\mathbf{v}_1(d) \quad c_{11}[\mathbf{v}_1(d)] \quad c_{12}[\mathbf{v}_1(d)] \quad c_{13}[\mathbf{v}_1(d)]) \in \mathbb{R}^4$
1205 $\mathbb{C}^{q(d) \times 4}$. We omit the degree indications $(d, d^{(2)})$ for the rest of the example for better
1206 readability. For $j = 1, 2$ it clearly holds $\bar{\mathbf{S}}^{(j)} \mathbf{v}_1 = x_j \cdot \bar{\mathbf{S}}^{(0)} \mathbf{v}_1$. For the second differential
1207 functional $c_{11} = \partial_{10}$, i.e. the 2nd column of $\tilde{\mathbf{V}}_1$, we have

$$1208 \quad c_{11}[x_j \mathbf{v}_1] = \partial_{10}[x_j \mathbf{v}_1] = x_j \partial_{10}[\mathbf{v}_1] + \phi_j(\partial_{10}[\mathbf{v}_1])$$

$$1209 \quad = x_j \partial_{10}[\mathbf{v}_1] + \begin{cases} \partial_{00}[\mathbf{v}_1] = \mathbf{v}_1 & : j = 1. \\ \mathbf{0} & : j = 2. \end{cases}$$

1211 Thus, $\bar{\mathbf{S}}^{(1)} c_{11}[\mathbf{v}_1] = \bar{\mathbf{S}}^{(1)} \tilde{\mathbf{V}}_1(:, 2) = \bar{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_1 \begin{pmatrix} 1 \\ x_1 \\ 0 \end{pmatrix}$ and $\bar{\mathbf{S}}^{(2)} \tilde{\mathbf{V}}_1(:, 2) = \bar{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_2 \begin{pmatrix} 0 \\ x_2 \\ 0 \end{pmatrix}$.

1212 Likewise, we find $\bar{\mathbf{S}}^{(1)} c_{12}[\mathbf{v}_1] = \bar{\mathbf{S}}^{(1)} \tilde{\mathbf{V}}_1(:, 3) = \bar{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_1 \begin{pmatrix} 0 \\ 0 \\ x_1 \end{pmatrix}$ and $\bar{\mathbf{S}}^{(2)} \tilde{\mathbf{V}}_1(:, 3) =$

1213 $\bar{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_1 \begin{pmatrix} 1 \\ 0 \\ x_2 \end{pmatrix}$. For the fourth functional c_{13} we have

$$1214 \quad c_{13}[x_j \mathbf{v}_1] = (2\partial_{20} + \partial_{11})[x_j \mathbf{v}_1] = x_j(2\partial_{20} + \partial_{11})[\mathbf{v}_1] + \phi_j(2\partial_{20} + \partial_{11})[\mathbf{v}_1]$$

$$1215 \quad = x_j c_{13}[\mathbf{v}_1] + \begin{cases} (2\partial_{10} + \partial_{01})[\mathbf{v}_1] = (2c_{11} + c_{12})[\mathbf{v}_1] & : j = 1. \\ \partial_{10}[\mathbf{v}_1] = c_{11}[\mathbf{v}_1] & : j = 2. \end{cases}$$

1217 Consequently, $\bar{\mathbf{S}}^{(1)} c_{13}[\mathbf{v}_1] = \bar{\mathbf{S}}^{(1)} \tilde{\mathbf{V}}_1(:, 4) = \bar{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_1 \begin{pmatrix} 0 \\ 2 \\ x_1 \end{pmatrix}$ and $\bar{\mathbf{S}}^{(2)} \tilde{\mathbf{V}}_1(:, 4) = \bar{\mathbf{S}}^{(0)} \tilde{\mathbf{V}}_1 \begin{pmatrix} 0 \\ 0 \\ x_2 \end{pmatrix}$.

1218 Collecting all these relations yields (46) with the upper triangular matrices

$$1219 \quad \mathbf{J}_1^{(1)} = \begin{pmatrix} x_1 & 1 & & \\ & x_1 & 2 & \\ & & x_1 & 1 \\ & & & x_1 \end{pmatrix} = x_1 \mathbf{I}_4 + \begin{pmatrix} 1 & & & \\ & 2 & & \\ & & 1 & \\ & & & 1 \end{pmatrix}, \quad \mathbf{J}_1^{(2)} = \begin{pmatrix} x_2 & 0 & 1 & \\ & x_2 & x_2 & 1 \\ & & x_2 & 0 \\ & & & x_2 \end{pmatrix}.$$

1220 Finally let's consider as one shift with a higher degree monomial the shift with the
1221 $(j = 3)$ rd monomial x_1^2 . It clearly holds $\bar{\mathbf{S}}^{(3)} \mathbf{v}_1 = x_1^2 \cdot \bar{\mathbf{S}}^{(0)} \mathbf{v}_1$. For the remaining
1222 columns we get

$$1223 \quad c_{11}[x_1^2 \mathbf{v}_1] = \partial_{10}[x_1^2 \mathbf{v}_1] = x_1^2 \partial_{10}[\mathbf{v}_1] + 2x_1 \mathbf{v}_1 = x_1^2 c_{11}[\mathbf{v}_1] + 2x_1 \mathbf{v}_1,$$

$$1224 \quad c_{12}[x_1^2 \mathbf{v}_1] = \partial_{01}[x_1^2 \mathbf{v}_1] = x_1^2 \partial_{01}[\mathbf{v}_1] = x_1^2 c_{12}[\mathbf{v}_1],$$

$$1225 \quad c_{13}[x_1^2 \mathbf{v}_1] = (2\partial_{20} + \partial_{11})[x_1^2 \mathbf{v}_1]$$

$$1226 \quad = 2(x_1^2 \partial_{20}[\mathbf{v}_1] + 2x_1 \partial_{10}[\mathbf{v}_1] + \mathbf{v}_1) + x_1^2 \partial_{11}[\mathbf{v}_1] + 2x_1 \partial_{01}[\mathbf{v}_1]$$

$$1227 \quad = 2\mathbf{v}_1 + 4x_1 c_{11}[\mathbf{v}_1] + 2x_1 c_{12}[\mathbf{v}_1] + x_1^2 c_{13}[\mathbf{v}_1].$$

1229 Hence,

$$1230 \quad \mathbf{J}_1^{(3)} = \begin{pmatrix} x_1^2 & 2x_1 & 2 \\ & x_1^2 & 4x_1 \\ & & x_1^2 & 2x_1 \\ & & & x_1^2 \end{pmatrix} = x_1^2 \mathbf{I}_4 + \begin{pmatrix} 2x_1 & 2 \\ & 4x_1 \\ & 2x_1 \end{pmatrix} = \mathbf{J}_1^{(1)2}.$$

1231

1232 B.2. Step 2. Establishing the BTD structure.

1233 *Proof of Theorem 4.2.* Recall that for $d \geq d^*$ the numerical basis $\mathbf{K}(d)$ of the
1234 Macaulay null space and the confluent multivariate Vandermonde matrix $\tilde{\mathbf{V}}(d)$ are
1235 linked by

$$1236 \quad \mathbf{K}(d) = \tilde{\mathbf{V}}(d) \mathbf{C}^T = (\tilde{\mathbf{V}}_1(d) \quad \dots \quad \tilde{\mathbf{V}}_{m_0}(d)) \begin{pmatrix} \mathbf{C}_1^T \\ \vdots \\ \mathbf{C}_{m_0}^T \end{pmatrix}$$

1237 and consider the matrix representation (18) of the third-order tensor $\mathcal{Y}(d^{(1)}, d^{(2)})$:

$$1238 \quad \mathbf{Y}_{[1,2,3]}(d^{(1)}, d^{(2)}) = \begin{pmatrix} \bar{\mathbf{S}}^{(0)}(d^{(2)}) \cdot \mathbf{K}(d) \\ \bar{\mathbf{S}}^{(1)}(d^{(2)}) \cdot \mathbf{K}(d) \\ \vdots \\ \bar{\mathbf{S}}^{(q(d^{(1)})-1)}(d^{(2)}) \cdot \mathbf{K}(d) \end{pmatrix} = \sum_{k=1}^{m_0} \begin{pmatrix} \bar{\mathbf{S}}^{(0)}(d^{(2)}) \cdot \tilde{\mathbf{V}}_k(d) \\ \bar{\mathbf{S}}^{(1)}(d^{(2)}) \cdot \tilde{\mathbf{V}}_k(d) \\ \vdots \\ \bar{\mathbf{S}}^{(q(d^{(1)})-1)}(d^{(2)}) \cdot \tilde{\mathbf{V}}_k(d) \end{pmatrix} \mathbf{C}_k^T$$

$$1239 \quad = \sum_{k=1}^{m_0} \begin{pmatrix} \tilde{\mathbf{V}}_k(d^{(2)}) \\ \tilde{\mathbf{V}}_k(d^{(2)}) \mathbf{J}_k^{(1)} \\ \vdots \\ \tilde{\mathbf{V}}_k(d^{(2)}) \mathbf{J}_k^{(q(d^{(1)})-1)} \end{pmatrix} \mathbf{C}_k^T = \sum_{k=1}^{m_0} (\mathbf{I}_{q(d^{(1)})} \otimes \tilde{\mathbf{V}}_k(d^{(2)})) \begin{pmatrix} \mathbf{I}_{\mu_k} \\ \mathbf{J}_k^{(1)} \\ \vdots \\ \mathbf{J}_k^{(q(d^{(1)})-1)} \end{pmatrix} \mathbf{C}_k^T$$

1241 with the upper triangular matrices $\mathbf{J}_k^{(j)}$, $j = 1 : q(d^{(1)})-1$, $k = 1 : m_0$ from [Lemma B.4](#)
1242 associated to the $q(d^{(1)})$ shifting monomials of degree 0 to $d^{(1)}$ which are assumed to
1243 be ordered consistently in the chosen monomial order. Consider the k th term in the
1244 above sum, which is associated to the k th root \mathbf{z}_k with multiplicity $\mu_k \geq 1$ and depth
1245 $0 \leq \delta_k \leq \mu_k - 1$. For the strictly upper triangular parts of $\mathbf{J}_k^{(i)} = x_i \mathbf{I}_{\mu_k} + \mathbf{N}_k^{(i)}$,
1246 $i = 1 : n$, we have the nilpotency properties

$$1247 \quad (54a) \quad (\mathbf{N}_k^{(1)})^{\alpha_1} \dots (\mathbf{N}_k^{(n)})^{\alpha_n} = \mathbf{0}_{\mu_k} \quad \forall \{\alpha_j\}_{j=1}^n \quad \text{with} \quad \sum_j \alpha_j > \delta_k$$

1248

1249 which include the individual properties

$$1250 \quad (54b) \quad (\mathbf{N}_k^{(j)})^\alpha = \mathbf{0}_{\mu_k}, \quad \alpha > \delta_k$$

1252 as special case. Furthermore,

$$1253 \quad (54c) \quad (\mathbf{N}_k^{(1)})^{\alpha_1} \dots (\mathbf{N}_k^{(n)})^{\alpha_n} = \eta \mathbf{e}_1 \mathbf{e}_{\mu_k}^T, \quad \eta \in \mathbb{C} \quad \text{if} \quad \sum_j \alpha_j = \delta_k.$$

1254

1255 Trivially, $(\mathbf{N}_k^{(j)})^{\mu_k} = \mathbf{0}_{\mu_k}$ since $\mu_k \geq \delta_k + 1$.

1256 Let $\mathbf{J}_k^{(j)}$ be associated to the monomial \mathbf{x}^{α_j} and express it in terms of the upper
1257 triangular matrices $\mathbf{N}_k^{(i)}$, $i = 1 : n$ by using the multi-binomial formula:

$$1258 \quad (55) \quad \mathbf{J}_k^{(j)} = \sum_{\mathbf{h} \leq \alpha_j} \mathbf{x}^{\mathbf{h}} \prod_{i=1}^n \binom{\alpha_i}{h_i} (\mathbf{N}_k^{(i)})^{\alpha_i - h_i} = \mathbf{x}^{\alpha_j} \mathbf{I}_{\mu_k} + \sum_{\substack{\mathbf{h} \leq \alpha_j \\ \mathbf{h} \neq \alpha_j}} \mathbf{x}^{\mathbf{h}} \prod_{i=1}^n \binom{\alpha_i}{h_i} (\mathbf{N}_k^{(i)})^{\alpha_i - h_i}.$$

1259

1260 Using above nilpotency properties (54) and also the property that all $\mathbf{N}_k^{(i)}$ commute
 1261 indicates that at most $q(\delta_k) - 1$ different products of strictly upper triangular matrices
 1262 appear in (55) (all products of powers of the $\mathbf{N}_k^{(i)}$ with $\sum_i (\alpha_i - h_i) > \delta_k$ cancel out).
 1263 The factors in front of the upper triangular matrices can be collected to match the
 1264 functional evaluations $c_{kl}[\mathbf{x}^{\alpha_j}]$, $l = 1 : \mu_k - 1$ so that every $\mathbf{J}_k^{(j)}$ can be written as

$$1265 \quad (56) \quad \mathbf{J}_k^{(j)} = \mathbf{x}^{\alpha_j} \mathbf{I}_{\mu_k} + c_{k1}[\mathbf{x}^{\alpha_j}] \hat{\mathbf{N}}_k^{(1)} + \cdots + c_{k, \mu_k - 1}[\mathbf{x}^{\alpha_j}] \hat{\mathbf{N}}_k^{(\mu_k - 1)}.$$

1267 Here, the $\hat{\mathbf{N}}_k^{(i)}$ are linear combinations of those $\mathbf{N}_k^{(h)} = \mathbf{J}_k^{(h)} - \mathbf{x}^{\alpha_h} \mathbf{I}_{\mu_k}$ that are asso-
 1268 ciated to shifting monomials \mathbf{x}^{α_h} with degrees equal to the differential order of c_{ki} ,
 1269 that is

$$1270 \quad \hat{\mathbf{N}}_k^{(i)} = \sum_{\{h : |\alpha_h| = o(c_{ki})\}} \omega_h \mathbf{N}_k^{(h)}, \quad \omega_h \in \mathbb{C}.$$

1271 Consequently, since the selection matrices $\bar{\mathbf{S}}^{(i)}$ are applied in the chosen monomial
 1272 order, we find

$$1273 \quad \begin{pmatrix} \mathbf{I}_{\mu_k} \\ \mathbf{J}_k^{(1)} \\ \vdots \\ \mathbf{J}_k^{(q(d^{(1)})-1)} \end{pmatrix} = \mathbf{v}_k(d^{(1)}) \otimes \mathbf{I}_{\mu_k} + c_{k1}[\mathbf{v}_k(d^{(1)})] \otimes \hat{\mathbf{N}}_k^{(1)} + \cdots + c_{k, \mu_k - 1}[\mathbf{v}_k(d^{(1)})] \otimes \hat{\mathbf{N}}_k^{(\mu_k - 1)}$$

$$1274 \quad = \left(\tilde{\mathbf{V}}_k(d^{(1)}) \otimes \mathbf{I}_{\mu_k} \right) \mathbf{G}_{k[1,2;3]}, \quad \mathbf{G}_{k[1,2;3]} \stackrel{\text{def}}{=} \begin{pmatrix} \mathbf{I}_{\mu_k} \\ \hat{\mathbf{N}}_k^{(1)} \\ \vdots \\ \hat{\mathbf{N}}_k^{(\mu_k - 1)} \end{pmatrix}. \quad \blacksquare$$

1276 Hence, one term of $\mathbf{Y}_{[1,2;3]}(d^{(1)}, d^{(2)})$ can be written as

$$1277 \quad (\mathbf{I}_{q(d^{(1)})} \otimes \tilde{\mathbf{V}}_k(d^{(2)})) \begin{pmatrix} \mathbf{I}_{\mu_k} \\ \mathbf{J}_k^{(1)} \\ \vdots \\ \mathbf{J}_k^{(q(d^{(1)})-1)} \end{pmatrix} \mathbf{C}_k^T = (\tilde{\mathbf{V}}_k(d^{(1)}) \otimes \tilde{\mathbf{V}}_k(d^{(2)})) \mathbf{G}_{k[1,2;3]} \mathbf{C}_k^T = \mathbf{Y}_{k[1,2;3]}$$

1278 which is a matrix unfolding of one term of a BTD $\mathcal{Y}_k(d^{(1)}, d^{(2)}) = \left[\mathcal{G}_k; \tilde{\mathbf{V}}_k(d^{(1)}), \tilde{\mathbf{V}}_k(d^{(2)}), \mathbf{C}_k(d) \right] \blacksquare$
 1279 of a third-order tensor $\mathcal{Y}_k(d^{(1)}, d^{(2)}) \in \mathbb{C}^{q(d^{(1)}) \times q(d^{(2)}) \times \mu_k}$. Since this holds for all
 1280 $k = 1 : m_0$, we established the BTD (19). The equality $\mathcal{G}_k(l_1 + 1, :, :) = \mathcal{G}_k(:, l_1 + 1, :)$
 1281 follows by symmetry. \square

1282 We illustrate this BTD construction in an example.

1283 **EXAMPLE B.6.** *Continuing the previous example Example B.5 with $d^{(1)} = d^{(2)} =$*
 1284 *2,*

$$1285 \quad \tilde{\mathbf{V}}_1(2) = (c_{10}[\mathbf{v}_1] \quad c_{11}[\mathbf{v}_1] \quad c_{12}[\mathbf{v}_1] \quad c_{13}[\mathbf{v}_1]) = \begin{pmatrix} -1 & 0 & 0 & 0 \\ x_1 & 1 & 0 & 0 \\ x_2 & 0 & 1 & 0 \\ x_1 & 2x_1 & 0 & 2 \\ x_1 x_2 & x_2 & x_1 & 1 \\ x_2 & 0 & 2x_2 & 0 \end{pmatrix}$$

1286 *with differential functions given in Example B.2, and upper triangular matrices $\mathbf{J}_k^{(j)}$*

1287 from the previous subsection. Now note that

$$\begin{aligned}
 1288 \quad \begin{pmatrix} \mathbf{I}_{\mu_1} \\ \mathbf{J}_1^{(1)} \\ \mathbf{J}_1^{(2)} \\ \mathbf{J}_1^{(3)} \\ \vdots \\ \mathbf{J}_1^{(5)} \end{pmatrix} &= \begin{pmatrix} \mathbf{I}_{\mu_1} \\ x_1 \cdot \mathbf{I}_{\mu_1} + \mathbf{N}_1^{(1)} \\ x_2 \cdot \mathbf{I}_{\mu_1} + \mathbf{N}_1^{(2)} \\ x_1^2 \cdot \mathbf{I}_{\mu_1} + 2x_1 \cdot \mathbf{N}_1^{(1)} + \mathbf{N}_1^{(1)2} \\ \vdots \\ x_2^2 \cdot \mathbf{I}_{\mu_1} + 2x_2 \cdot \mathbf{N}_1^{(2)} + \mathbf{N}_1^{(2)2} \end{pmatrix} = \begin{pmatrix} \mathbf{I}_{\mu_1} \\ x_1 \cdot \mathbf{I}_{\mu_k} + c_{11}[x_1]\hat{\mathbf{N}}_1^{(1)} + c_{12}[x_1]\hat{\mathbf{N}}_1^{(2)} + c_{13}[x_1]\hat{\mathbf{N}}_1^{(3)} \\ x_2 \cdot \mathbf{I}_{\mu_1} + c_{11}[x_2]\hat{\mathbf{N}}_1^{(1)} + c_{12}[x_2]\hat{\mathbf{N}}_1^{(2)} + c_{13}[x_2]\hat{\mathbf{N}}_1^{(3)} \\ x_1^2 \cdot \mathbf{I}_{\mu_1} + c_{11}[x_1^2]\hat{\mathbf{N}}_1^{(1)} + c_{12}[x_1^2]\hat{\mathbf{N}}_1^{(2)} + c_{13}[x_1^2]\hat{\mathbf{N}}_1^{(3)} \\ \vdots \\ x_2^2 \cdot \mathbf{I}_{\mu_1} + c_{11}[x_2^2]\hat{\mathbf{N}}_1^{(1)} + c_{12}[x_2^2]\hat{\mathbf{N}}_1^{(2)} + c_{13}[x_2^2]\hat{\mathbf{N}}_1^{(3)} \end{pmatrix} \\
 1289 \quad &= c_{10}[\mathbf{v}_1] \otimes \mathbf{I}_4 + c_{11}[\mathbf{v}_1] \otimes \hat{\mathbf{N}}_1^{(1)} + c_{12}[\mathbf{v}_1] \otimes \hat{\mathbf{N}}_1^{(2)} + c_{13}[\mathbf{v}_1] \otimes \hat{\mathbf{N}}_1^{(3)},
 \end{aligned}$$

1291 which corresponds to (56) with

$$1293 \quad \hat{\mathbf{N}}_1^{(1)} \stackrel{\text{def}}{=} \mathbf{N}_1^{(1)}, \quad \hat{\mathbf{N}}_1^{(2)} \stackrel{\text{def}}{=} \mathbf{N}_1^{(2)}, \quad \hat{\mathbf{N}}_1^{(3)} \stackrel{\text{def}}{=} \frac{1}{2}\mathbf{N}_1^{(1)2} = \mathbf{N}_1^{(1)}\mathbf{N}_1^{(2)}.$$

1294 Consequently,

$$\begin{aligned}
 1295 \quad (\mathbf{I}_{q(d^{(1)})} \otimes \tilde{\mathbf{V}}_1(d^{(2)})) \begin{pmatrix} \mathbf{I}_{\mu_1} \\ \mathbf{J}_1^{(1)} \\ \vdots \\ \mathbf{J}_1^{(q(d^{(1)})-1)} \end{pmatrix} &= (\mathbf{I}_{q(d^{(1)})} \otimes \tilde{\mathbf{V}}_1(d^{(2)})) \left(c_{10}[\mathbf{v}_1] \otimes \mathbf{I}_4 + c_{11}[\mathbf{v}_1] \otimes \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{pmatrix} \right. \\
 1296 \quad &\quad \left. + c_{12}[\mathbf{v}_1] \otimes \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} + c_{13}[\mathbf{v}_1] \otimes \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \right) \\
 1297 \quad &= (\tilde{\mathbf{V}}_1(d^{(1)}) \otimes \tilde{\mathbf{V}}_1(d^{(2)})) \underbrace{\begin{pmatrix} \mathbf{I}_4 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}}_{=\mathbf{G}_{1[1,2;3]}}.
 \end{aligned}$$
